of secretion due to the caffeine alone. Thus caffeine has a potentiating action which is still present 40-60 minutes after it has been injected. Since these doses of caffeine have only a slight, if any, secretory stimulant action, the two sets of results have been combined to obtain average figures from 13 animals. A typical graph of the secretory response to histamine before and after caffeine is shown in the Chart.

**Theobromine and Theophylline**—Results with these two xanthine derivatives were much more variable than those with caffeine. The histamine effect was appreciably increased after theobromine in three out of six cats (Table II). In one of these (No 90) free acid secretion due to histamine was increased from 1.2 to 36.25 ml of N/50 HCl. In cat No 93 theobromine had some stimulant effect itself, but there was no significant increase in the effect of histamine after theobromine. The smaller effect of histamine after theobromine in cat No 89 cannot be attributed to the theobromine, since second doses of histamine often have less effect than the first dose. There was some

secretory response after theophylline in two, or possibly three, out of six animals (Table III). In one of these (No 86) the histamine effect was very greatly increased after theophylline, there being five-fold and twenty-fold increases respectively in the volume of juice and free acid secreted. In this animal theophylline itself had a stimulant effect on secretion. There was a possible potentiation in cat No 85.

Chart showing the effect of histamine (0.35 mg subcutaneously) on gastric secretion before and after a dose of caffeine (20 mg per kg) which did not stimulate secretion. Juice measured at intervals of 10 minutes (cat No 81, weight 2 kg).

The effect of histamine was less consistently altered after theobromine or theophylline than after caffeine, but occasionally there was a considerable increase.

**Controls**—In control experiments repeated injections of a dose of histamine at intervals of one or two hours never gave an increasing response. Indeed, as Roth and Ivy (1944e) and others have indicated, there was a tendency towards a reduction in the secretory response to successive doses of histamine. Thus an increased effect of histamine after caffeine, etc., may be fairly attributed to the xanthine compound but a reduction in the effect of histamine as in cats Nos 87 and 89 is probably not due to the xanthine compound. Inspection of the gastric mucosa at the end of the experiment confirmed the findings of Roth and Ivy (1945). There was obvious hyperaemia and engorgement of the mucosa, particularly in those animals treated with caffeine. No quantitative estimate of the change was made, but it appeared much less after theophylline or theobromine. No similar effect was observed in the mucosa of any cat after repeated histamine injections or after continuous histamine infusion for several hours.

### Discussion

Roth and Ivy showed that caffeine stimulates gastric secretion in the cat and also acts synergistically with histamine. They suggest that "the stimulation of gastric secretion may not necessarily be attributed to the same property of caffeine which is responsible for the synergism," since the synergistic action persists when the stimulant action of caffeine is over. The present results, showing that in doses which have no stimulant action on gastric secretion caffeine can potentiate the effect of histamine, support the probability that some other mechanism is responsible. Roth and Ivy (1945) have suggested that persistently increased blood flow accompanying vasodilatation might be a factor. Their later observations on the vascularity of the mucosa after caffeine strengthened this view. Observations on ulcers induced by caffeine in cats led them to suggest the following sequence of events caused by caffeine in the gastric mucosa: "vasodilatation and engorgement, vascular stasis, local anoxia, increased capillary permeability, transudation, exudation and decreased cell nutrition." The vascular and cellular changes due to caffeine may make the mucosa more susceptible to the proteolytic action of acid and pepsin secretion.

The present results with theobromine and theophylline are less consistent and convincing. There is evidence that theophylline at least is a more potent vasodilator than caffeine and it might have been expected to be at least as active as caffeine in potentiating the secretory action of histamine. To that extent this affords some evidence that the effect on blood flow is not necessarily the cause of the

potentiating effect of caffeine. It is known that caffeine increases the oxygen uptake of resting frog muscle and that this increase is sensitive to azide (Stannard 1939). It may be that caffeine also has some effect on an intracellular enzyme system concerned in gastric secretion, and this may underlie the potentiating effect of caffeine on histamine-induced gastric secretion. Whatever the explanation of the observed effect, certain conclusions are permissible. Even if histamine is not intimately concerned in either the physiology or pathology of gastric secretion, then consumption of large amounts of caffeine-containing drinks may be a factor in peptic ulcer formation or perpetuation. If histamine is associated with normal gastric secretion or with ulcer formation then the danger of excess caffeine intake is increased. It is still not justifiable, as Roth and Ivy (1946) stress, to conclude from the experimental results in animals that caffeine can cause peptic ulceration in man. It is known, however, that after a caffeine test-meal secretion of acid gastric juice is greater and more prolonged in ulcer patients than in normals (Roth, Ivy, and Atkinson, 1944).

The present experiments in normal cats show that caffeine potentiates the action of histamine on gastric secretion, and that theobromine and theophylline can have a similar action in some animals. Our results support Roth and Ivy's (1944b) conclusion that ulcer patients should restrict their intake of beverages containing caffeine, and also suggest that it is desirable to limit their consumption of foods and drinks containing theobromine and theophylline. These substances should equally be avoided by the patient with hyperchlorhydria but no ulcer.

### Summary

Caffeine injected intravenously in a dose which does not usually stimulate gastric secretion in the anaesthetized cat consistently potentiates the gastric stimulant action of histamine.

A similar but less consistent effect was observed after theobromine and after theophylline.

The significance of these findings is discussed in relation to the management of the patient with peptic ulcer.

It is a pleasure to acknowledge the encouraging help given by Professor E. J. Wayne and the technical assistance of Mr. E. Salvin.

Mr. John Edwards, Parliamentary Secretary to the Ministry of Health, paid tribute to the work of insurance committees when he addressed members of the London Insurance Committee on July 1 at their last meeting. "I think the finest tribute to their work is the decision to base much of the new health service on the existing arrangements. Without the co-operation of insurance committees it would have been very difficult for executive councils to prepare for the new scheme. They have most generously assisted executive councils from the very beginning by making the services of their staff available and by placing their offices and equipment at the councils' disposal. Wherever possible the Minister has included insurance committee members among his appointments to executive councils. I am quite sure that their experience will help to guide the councils over the difficult transitional period and ensure the continuity of administration which we are anxious to maintain." London, he said, had faced a special task. "Not only have you the largest register in the country but you also have the largest number of doctors and chemists in contract with you. I understand that there are 1,675 doctors on your list and that the chemists in contract with you have some 1,200 shops. Indeed, the magnitude of everything in London is always a challenge to those responsible for administration—a challenge which your committee has always successfully accepted."

## RECTAL CANCER AND PRESERVATION OF FUNCTION\*

BY

E G MUIR, MS, FRCS

*Surgeon King's College Hospital*

No single standard operation is suitable for all cases of rectal or recto-sigmoid cancer, for the operation should be planned to suit the rectum rather than the rectum cut to suit the plan. The ideal is the efficient removal of the growth with preservation of normal defaecation. A permanent colostomy is not too high a price to pay for the efficient removal of a rectal cancer provided it is essential, it is a heavy burden if it is not. Clinical surgery suggests, and pathology supports the view, that in a number of these cases the internal sphincter, that mechanism of continent defaecation, is needlessly sacrificed through devotion to a stereotyped operation. At the same time it is salutary to remember that some surgeons have in the past abandoned anastomotic operations through the fear and the experience that such methods sometimes lead to an inefficient extirpation of the growth.

### History

An operation to excise a rectal growth and preserve a functioning anus is no novelty, it is probable that it was a more fashionable ambition for the surgeon in the past century than it is now. Even a brief study of the literature on this subject makes it apparent that it would now be almost impossible to devise a truly original operation of this type, save perhaps in its minor details. The ingenuity of many surgeons has explored every conceivable route. Extensive reviews of the literature have been made by Bacon (1945), d'Allaines (1946), and many others. It will suffice here to mention some of the methods which seem to have influenced the present trend of surgical opinion.

It was not until the latter part of the last century that excision of the rectum became common. Though not the first, one of the more interesting of the early attempts to perform a resection-anastomosis on a rectal growth is that described by Maunsell in 1892. The rectum was mobilized through the abdomen and was then prolapsed through a dilated anal orifice to an assistant working in the perineum, who divided the outer layer of the prolapse, pulled down the growth, and performed a resection-anastomosis. Maunsell's immediate post-operative treatment consisted in making his patients drink large quantities of hot water, for he had found that he "had more success with hot water than with any other remedy." However unusual the post-operative treatment of half a century ago may seem to-day, the steps which Maunsell described have been the basis for many subsequent methods. Rayner (1935) quotes Sebrecht as utilizing the abdominal mobilization followed by the dissection upwards of the rectal mucosa from the mucocutaneous junction and the suture of the sigmoid to the anal canal. In 1908 Miles introduced the abdomino-perineal operation, and this discouraged attempts to restore anal function, at least in this country. In 1932 Babcock described the operation of procto-sigmoidectomy without preliminary colostomy, the salient features being the abdominal mobilization, excision of the lymphatic field at a high level, the perineal approach from within the external sphincter, and the removal of the internal sphincter, the sigmoid being brought out as a terminal colostomy through

the anus. Devine (1937) advocated a preliminary transverse colostomy followed by resection and anastomosis on a clean and empty bowel. Dixon (1944) and Wangenstein (1945) have adopted a purely abdominal approach in suitable cases. Lockhart Mummery (1908), Pannett (1935), and others have described combinations of the abdominal and perineal approach, and Lloyd-Davies (1939) has described a "pull-through" method with drainage of the presacral space through the anastomotic line.

It will be apparent from even this superficial survey that the surgeon who essays resection and anastomosis for a rectal growth has a wide choice of operation. Fortunately it is no shame to follow another's path—to be original it is necessary only to think for oneself and not necessarily unlike everyone else. He who constantly performs the same operation sometimes acquires not only dexterity in his particular method but a reluctance to attempt another. Certain aspects of this type of operation require special consideration, from these we must draw our personal conclusions.

### The Sphincter Mechanism

Milligan and Morgan (1934) have made a careful study of the internal and external sphincters, and it is generally accepted that perfect continence requires an intact ano-rectal ring—that condensation of the circular muscle fibres of the rectum in association with the pubo-rectalis fibres of the levator ani muscle. It is true that Bacon and Babcock rely on the external sphincter for control after procto-sigmoidectomy, sutured round the sigmoid colon two to four weeks after resection. They state that 80% of their patients may be classified as continent, though 40% wear a protective perineal pad. While there can be no doubt that a varying degree of control may be obtained from the external sphincter even after it has been divided and repaired, certain continence requires an intact ano-rectal ring and, since the sense of perception is important, an intact lining to the anal canal. A good abdominal colostomy is probably better than an incontinent or untrustworthy anus.

### Essential Pathological Requirements

We owe to Miles the first sound description of the pathology of rectal cancer and its implications on its surgical removal. He stressed the lymphatic spread upwards in association with the superior haemorrhoidal artery, laterally with the middle haemorrhoidal vessels, and downwards with the inferior haemorrhoidal vessels. Subsequent pathological studies, while bearing out the importance of the upward spread, have shown that Miles laid undue stress on the frequency of lateral and downward lymphatic spread. The work of Gabriel, Dukes, and Bussey (1935), Gilchrist and David (1938), and Collier, Kay, and McIntyre (1940) has shown that the main lymphatic spread of rectal cancer is in an upward direction, lateral and downward spread taking place only when the lymphatic system above is blocked by growth. Few lymphatic glands over 1 in (2.5 cm) below a rectal growth are likely to contain metastases, still less those 2 in (5 cm) below, and it would seem to be a reasonable conjecture that a distance of 2½ to 3 in (6.25 to 7.5 cm) below a growth is outside its lymphatic spread except in advanced cases. Here the involvement of the glands above the growth is likely to be such that complete removal of infected glands is impossible and any retrograde spread will be of secondary importance.

Dukes (1944) has demonstrated that 17% of rectal growths excised show involvement of the adjacent veins, though this does not necessarily denote hepatic metastases. He has also shown that the cancer cells may grow down the lumen of a vein in a retrograde manner, appearing sometimes as

\*Based on a lecture delivered at the British Postgraduate School, Hammersmith

a nodule of carcinoma in the mucosa below a growth. While this retrograde venous spread is probably uncommon, and such cases must inevitably have a rather poor prognosis, it is an additional reason for removing a margin of normal bowel below a growth.

There is a further pathological consideration to an operation of anastomosis. It is well known that adenomata are often found in the neighbourhood of a rectal cancer, and two primary growths are not uncommon. Some years ago, when pointing out the advantages of a purely abdominal resection for recto sigmoid and high rectal growths in infirm patients, I drew attention to the possibility of another growth developing in the rectal stump (Muir, 1939). Gabriel and others have since recorded cases in which a carcinoma developed in this site after an abdominal excision. An abdomino-perineal or other combined operation removes completely the rectum and the greater part of the sigmoid colon, but the surgeon who performs an anastomotic operation must bear in mind the possibility, however small, of another primary growth developing from an adenoma in the rectal stump, or indeed in the remaining portion of the sigmoid colon. It is probable that the majority of patients would prefer to accept this risk rather than a permanent colostomy, but the presence of numerous adenomata below a high rectal growth should be regarded as a contraindication to the retention of any rectal mucosa and therefore to an anastomotic operation. The removal of all rectal mucosa while it has other disadvantages, is in this respect a point in favour of the Babcock-Bacon operation.

The essential pathological requirements for an anastomotic operation are that the lymphatic drainage system of the rectum must be removed at its highest practical level by ligation of the inferior mesenteric artery either between the sigmoid branches or immediately below the last sigmoid branch, that the division of the bowel must be at least 2½ to 3 in. below the growth, and that the presence of numerous adenomata below the growth contraindicates this type of operation.

There are perhaps two occasional exceptions to these rules: the operable growth with small hepatic metastases, and the small growth in the rectal ampulla which clinically appears to be an 'A' case. In both these cases there are strong grounds for trying to preserve a functioning anus even if such methods of resection necessitate a reduction in the margin of normal bowel below the growth.

#### Frequency of Cases Suitable for Resection-anastomosis

Bacon, analysing the site of the growth in 1401 cases of rectal recto-sigmoid and sigmoid carcinomata considered that over 80% were suitable for resection with preservation of a functioning anus. It should be remembered when considering these figures that Bacon accepts every growth 3 cm. above the ano-rectal line or 6 cm. above the anal margin as suitable for procto-sigmoidectomy, that the internal sphincter is not preserved in this operation, and that sigmoid growths are included in this series. Such sigmoid growths might well be those requiring ligation of the inferior mesenteric artery for their proper removal, but even if they (315) are excluded, 1086 cases of rectal and recto-sigmoid cancer remain. Of these 231 were recto-sigmoid: 148.5 in (125 cm.) and 211.4 in (10 cm.) from the ano-rectal line. Thus 590 or more than half might appear suitable at least in theory for a method of resection-anastomosis which preserved the internal sphincter.

Clinically, growths just palpable at the tip of the finger or discovered only on sigmoidoscopy are usually suitable. The prolapse of a recto-sigmoid growth may be misleading.

A growth 2 to 3 in. above the cervix or vesicles may appear suitable but in many cases a final decision can be made only at laparotomy. The rectum is not a straight tube, but undulates from side to side, lying curved in the hollow of the sacrum, a growth easily accessible on rectal examination may lie at the level of the abdominal wall when the rectum has been fully mobilized. In general, apart from being operable growths suitable for these operations should lie at least 2 to 3 in. (5-7.5 cm.) above the lowest level of peritoneal reflection in the pouch of Douglas, though this peritoneal level is by no means constant in its distance from the ano-rectal ring. Growths of the rectal ampulla are unsuitable for operations of this type.

#### The Sigmoid Colon

Since it is necessary to ligate the inferior mesenteric artery either above or immediately below the last sigmoid branch, the blood supply to the distal sigmoid may be jeopardized. In one of my cases, intended for an anastomotic operation, ligation obliterated the arterial supply to the greater part of the sigmoid, and it became necessary to perform an abdomino-perineal resection. A good blood supply is essential to that part of the sigmoid which is to be brought down to the rectal stump or anal canal. After ligation some surgeons have advised marking the most distal part of the sigmoid with visible pulsation by means of a silk stitch. Poor vascularity is associated with infection and is far less likely to cause trouble when no actual suturing is used as in "procto-sigmoidectomy," or when the operation is performed on a clean, empty, and non-functioning bowel.

A long and mobile sigmoid is of great assistance; an unusually short bowel or diverticulitis may render the operation impossible. The length of the sigmoid is of more importance in a "pull-through" method than in a purely abdominal resection and anastomosis when sufficient bowel can usually be obtained by mobilizing it in the left iliac fossa. A pre-operative estimate of the length and condition of the sigmoid can be obtained by a barium enema.

#### Preliminary Colostomy

A preliminary transverse colostomy, as advocated by Devine, permits the operation to be performed on a non-functioning and through the use of lavage and sulphaphthaladine, an almost sterile bowel. A left iliac colostomy "takes in slack" and reduces the mobility of the sigmoid.

A preliminary colostomy is not a routine in all methods. It is unnecessary in the Babcock-Bacon technique, where a terminal colostomy is established through the anus without bowel-suturing. Nor is it used by Wangenstein in his method of abdominal resection and anastomosis, employing deep pelvic clamps. d'Allaines performs colostomy at the time of the resection, on the grounds that a defunctionalized bowel is shorter, shrunken, and more difficult to anastomose.

Necrosis and infection are not only more likely but are also more dangerous when they occur in functional bowel. A preliminary colostomy will require closure, and its use may add three to four weeks to a patient's stay in hospital, but it adds such a degree of safety to these operations that I regard it as essential.

#### The Route

The necessity for removing the lymphatic field at its highest level makes abdominal mobilization an essential part of the operation. The resection may be carried out from the abdomen alone, thus requiring an anastomosis

between the sigmoid and the rectal stump in the depths of the pelvis, or the abdominal mobilization may be combined with a perineal anastomosis. This may be performed above the levator muscles, aided by their partial division, or outside the anal canal, by prolapsing the rectum, the growth, and the sigmoid through a dilated anus. Finally, as in procto-sigmoidectomy, the sigmoid may be brought out as a terminal colostomy through the anal orifice. My personal choice is for two methods: abdominal resection and anastomosis without clamps, which I believe to be applicable to the majority of suitable cases, and a "pull-through" resection, which, at least in my hands, requires a long sigmoid.

**Abdominal Resection and Anastomosis without Clamps**—The use of clamps deep in the pelvis presents considerable difficulties. I have not had the opportunity of using those devised by Wangenstein for this purpose, but any clamp in this situation takes up valuable room and leaves devitalized tissues. I think it is therefore preferable to dispense with clamps for the purpose of the anastomosis. This operation is suitable for recto-sigmoid growths and many of those in the upper third of the rectum. A preliminary transverse colostomy is performed 14 days before the resection (combined with laparotomy if there is any doubt whether the case is suitable) and the distal bowel cleared by wash-outs and sulphaphthaladine emulsion. The first step in the resection consists in placing the patient in the lithotomy position and carefully swabbing out the rectum. The coccyx is removed and a corrugated drain introduced through the presacral fascia into the presacral space behind the rectum. Drainage should be provided for an anastomosis performed under some difficulty and surrounded by loose cellular tissue, and this is best obtained through the space left after excision of the coccyx. The patient is then placed in the full Trendelenburg position and the initial stages of the usual abdomino-perineal operation are performed. Before ligating the vascular pedicle the blood supply of the sigmoid loop should be carefully examined, bearing in mind the length of the mesosigmoid and the distance to which it must reach. As a rule I have ligated between the sigmoid branches where there is a long and mobile sigmoid and below the last sigmoid branch where the bowel is short.

The effect of this ligation will become evident on the sigmoid colon while the rectum is mobilized. This is carried out to a low level, anteriorly from the vagina or pros-

FIG 1—Clamp and retractor applied. The proposed line of incision in anterior rectal wall is shown.

FIG 2—Anterior rectal wall divided. Two cobbling "stay" sutures are inserted.

tate, posteriorly, and laterally. A hysterectomy clamp, which takes up less room in the pelvis than any other, is applied 3 in. below the growth, and an assistant working from the perineum once more carefully swabs out that part of the rectum below the clamp. With the bowel on traction, the anterior wall of the rectum is now opened below the clamp (Fig 1). Two cobbling "stay" sutures are inserted on each side (Fig 2), the posterior wall of the

rectum is divided, and two further sutures are inserted. These sutures serve to hold the rectal stump, to narrow the lumen of the rectal ampulla, which is larger than the sigmoid, and to prevent eversion. A point on the sigmoid with a good blood supply is selected, the mesosigmoid divided, and the sigmoid cut obliquely and anastomosed to the rectal stump (Fig 3). Penicillin-sulphathiazole powder is sprayed around the anastomosis and the pelvis peritoneum is sutured over it and to the sigmoid colon.

**The "Pull-through" Re-section**—The essential features of this operation have been described. Its disadvantage is that a long sigmoid is of considerably more importance than in the preceding operation. Its advantage, that it enables the surgeon to divide the bowel still closer to the ano-rectal ring. As an alternative to the "synchronous combined" position adopted by Lloyd-Davis (1945), the abdominal part may be first completed, the patient being subsequently placed in the lithotomy position. As in the preceding operation, I prefer drainage through the coccygeal space with complete suture of the anastomosis. After both these operations the transverse colostomy will require closure. Two to four weeks appears to be a suitable interval if the anastomosis is sound. I do not believe a long delay to be either necessary or desirable in the majority of cases.

FIG 3—Four "stay" sutures are in position. Anastomosis with sigmoid has begun.

## Results

The personal series here reviewed is of 86 consecutive cases of rectal and recto-sigmoid cancer operated upon since the war. Too small in number and too recent for any consideration of the end-results, they serve to show the frequency with which suitable cases may occur.

Abdomino-perineal or other combined operation	49
Abdominal resection and anastomosis	18
"Pull through" resection and anastomosis	3
Abdominal resection (Hartmann)	1
Perineal resection (palliative)	1
Inoperable	14

Operability rate 84%  
(Two patients upon whom resection was performed had small hepatic secondaries)

It will be seen that about one-third of the cases considered operable were found suitable for an anastomotic operation. I believe this percentage is too high: two of my cases should have had a combined operation. The abdomino-perineal is likely to remain the most common surgical attack against rectal cancer.

**Complications**—Pelvic infection, fistula, stricture, and incontinence are the more serious complications which might follow these anastomotic operations. Necrosis of the rectal stump through interference with its blood supply has been described by Dixon. If the lateral ligaments of the rectum are fully divided the middle haemorrhoidal arteries must be severed and the rectal stump will depend mainly on the inferior haemorrhoidal arteries for its blood supply. These complications are less likely to occur and will be much less serious in their effects when the operation is performed on a non-functioning and "sterile" bowel. The last two patients upon whom I performed "resection-anastomosis" both developed fistulae. One of these was into the vagina, now happily healed, while the other was into the presacral space. These have been the only fistulae in this series.

The healed anastomotic ring, easily palpable on rectal examination, is always smaller than the rectal ampulla, since it is the junction with the sigmoid. I have had several cases with a small anastomosis, but none have yet required dilatation with bougies. All anastomotic cases have been left with full control. There has been some rectal prolapse after the operation in two of my cases, and this complication has been noted by others.

**Mortality**—There have been two deaths in this short series, in which 72 cases were submitted to some form of resection. Assuming a high operability rate, all operations for rectal cancer must carry a definite mortality, having regard to the age group of these patients. However, the mortality has altered very considerably during the past 20 years. Those who had the privilege of watching Miles perform his operation know that this is not due to any improvement in surgical technique but to the surgical aids and in particular to the sulphonamides and penicillin. The danger from sepsis, considerable in the past, is now small. The mortality rate of these operations should now be not more than 5%.

**End-results**—The end-results of operations for rectal cancer which preserve a functioning anus have been discussed by Babcock, Bacon, Dixon, and others. d'Allaines,

FIG 4

Lloyd-Davies (1948) has recently described recurrences in "A" cases taking place at the suture line.

I have at present a patient upon whom I performed an abdominal resection and anastomosis for a high rectal growth two years ago. Examination of the operation specimen showed that an adequate length of bowel had been resected, all glands examined below the growth appeared free, but metastases were present in a gland at the highest level. This patient, a woman of 59, recently developed a polypoid carcinoma at the anastomotic site and a full abdomino-perineal resection has now been performed (Fig 4). I am indebted to Dr Cuthbert Dukes for the following report:

The specimen measured 11 in (28 cm) and consisted of a portion of the pelvic colon and the rectum. The line of

anastomosis from the original operation could be clearly seen about 3½ in (8.75 cm) above the ano-rectal line. There was a slight narrowing of the lumen in this region, but otherwise the mucosal surface looked normal except for a protuberant tumour half an inch (1.25 cm) in diameter situated on the posterior quadrant. The tumour was attached to the mucous membrane by a broad pedicle, and from its general appearance it certainly seemed to be derived from the mucous membrane. In its gross characters the tumour appeared to be a pedunculated adenoma of doubtful malignancy. There was no evidence of extension into the adjacent perirectal tissues, which, however, were tough and fibrous.

Section shows the tumour to be an adenocarcinoma very well differentiated in character and, judged from its histology, of a relatively low grade of malignancy. There is evidence of spread to the submucous coat and slight invasion of the rectal muscle only. Sections cut through the thickened extra-rectal tissues show fibrosis and inflammatory infiltration but no sign of carcinoma. There was no sign of venous spread. Seven lymphatic glands were found and sectioned, but these were all free from metastases.

This is undoubtedly either a fresh primary tumour or the result of an implantation at the site of anastomosis of the previous operation.

If implantation is the cause of this type of recurrence it behoves the surgeon to exercise the greatest care in his technique, but it is a risk to which all bowel surgery for cancer must be exposed to some degree. By comparison I have two other patients who underwent an abdomino-perineal resection for rectal cancer within the past year and who have now developed fresh growths at and just above the terminal colostomy. These are surely examples of the inevitable and deadly trend of unhealthy and precancerous bowel. An abdomino-perineal operation will give increased protection against a further growth, but may not prevent it. Apart from the presence of obvious adenomata, our present knowledge does not allow us to predict when the retention of any rectal mucosa is fraught with any danger to a patient, though there are some who would say, "Always!"

Apart from the foregoing, it is germane to remind ourselves of several other points in the prognosis of rectal cancer. A high operability rate will almost certainly mean a reduced survival rate. It is known that if the lymphatic glands are not involved at the time of operation the prognosis is relatively good, in such cases the amount of bowel removed below the growth is not likely to affect the issue materially from this aspect. If at operation the glands are already involved the ultimate prognosis is less satisfactory, though considerably better with high removal of the lymphatic field than with a perineal resection. The operations which aim at the preservation of normal defaecation do remove the main lymphatic drainage system of the rectum to the same high level as an abdomino-perineal excision. If therefore a judicious selection of cases is made there is little reason why the results should not be comparable and a permanent colostomy be avoided in certain cases of rectal and recto-sigmoid cancer.

### Conclusions

There is a sound pathological basis for operations which aim at preserving a functioning anus in high rectal and recto-sigmoid growths, but even in early cases and with adequate excision carcinoma can reappear at the anastomotic site.

To be certain of continence the ano-rectal ring must be preserved.

Of the various methods abdominal resection-anastomosis and a "pull-through" resection appear preferable.

A preliminary transverse colostomy lessens the risk and dangers of infection and should always be employed.

The use of sulphonamides and penicillin has reduced the mortality of all methods of rectal resection to a low figure.

## THE CLINICAL FEATURES OF MUSTARD-GAS POISONING IN MAN

BY

D C SINCLAIR, MA, MD

(From the Department of Anatomy University of Oxford)

The occurrence of general systemic symptoms following exposure to heavy dosages of mustard vapour or to massive liquid contamination was well recognized in the 1914-18 war. Since then experimental work on the subject has been largely concerned with the pathological changes observed in animals following the administration of mustard gas by different routes. These investigations have been reviewed by Smith (1943), who gives a comprehensive account of the literature.

In the absence of any large body of human experimental material, investigations on the changes in the haemopoietic system and blood chemistry of animals have tended to relegate to the background the clinical symptomatology produced in man by exposure to mustard gas. Isolated cases of accidental exposure have occurred from time to time, and some have been reported in the medical press (Hobbs, 1944). In these also, however, attention has been focused on the pathology rather than on the symptoms, many of which are nevertheless of the greatest importance, since their occurrence in the case of mustard-gas burns throws light on the mechanism by which similar symptoms arise following thermal burns.

It is difficult to demonstrate the occurrence of systemic manifestations in cases of slight or moderate mustard burns in temperate climates. In the Tropics, however, systemic poisoning by mustard gas is much more readily produced. From 1943 to 1945 I had the opportunity of observing a series of 438 volunteers exposed to mustard gas under tropical conditions, and thus of becoming familiar with the clinical picture of systemic mustard-gas poisoning.

### Material and Methods

Of the 438 men observed 320 were exposed to mustard vapour and 118 to contamination by liquid mustard. In both the vapour and liquid groups the resultant burns were of all degrees of severity, ranging from a faint erythema of a localized area of skin to multiple ulcers many hundreds of square centimetres in area. All the men exposed to vapour and 77% of those exposed to liquid wore fully effective respirators throughout exposure.

The occurrence of systemic poisoning in these men was assessed both objectively, by daily clinical examination for a minimum period of 21 days after exposure, and subjectively, by daily interrogation. Each man was examined separately, and was asked only, "How are you feeling to-day in yourself?" No leading questions or suggestions were used.

Not all the symptoms of which the volunteers complained were easy to evaluate. Great care, however, was taken in each case to exclude adventitious causes, such as indulgence in the local mixture of lower alcohols, and to sort out genuine complaints from those which might be regarded as suspicious. In general, it was impossible to assign any accurate degree of severity to the subjective clinical symptoms owing to the variation in the general character and education of the volunteers. It is felt that considerable confidence can be placed in the findings, since they were recorded in men classified as A1 who were in good physical condition and well acclimatized to the Tropics. Further, the men had all volunteered to be exposed to mustard gas, and showed the keenest interest in the work.

Owing to lack of time and facilities it was only possible to follow blood changes in selected groups of men. The clinical pathology of some of the severely affected men was more extensively investigated.

### Observations

#### Threshold and Severity

No symptoms attributable to systemic poisoning occurred in any vapour case in which no lesion more severe than erythema developed. There were 84 such men. Similarly, no man with liquid burns in whom the total raw surface ultimately produced was less than 20 square centimetres in area complained of systemic symptoms. In this category 83 men were included. Of the remaining 271 men, 102 reported one or more symptoms.

The severity of the effects varied within wide limits. In 35 men systemic manifestations were present on one day only, and in most of these cases the symptoms were in no way incapacitating. At the other extreme were cases in which systemic symptoms were a major factor in producing prolonged disability. In 37 men never more than one symptom was present, while the remaining 65 complained of two or more symptoms at various times. In general, the latter group included the more severely affected men.

#### Time Factors

Of the 102 men affected 66 (65%) showed symptoms within 24 hours of exposure, 83 (81%) were involved within 48 hours and 96 (94%) before the sixth day. It is also of interest that only 3 (16%) of the 19 cases in which the onset of symptoms occurred later than 48 hours after exposure could be described as more than very slightly affected. In contrast the onset of systemic symptoms in some of the worst cases preceded even the appearance of erythema of the skin.

Fig 1 shows the number of men complaining of one or more systemic symptoms on each day after exposure. The number is largest on the first day, and falls fairly regularly till the end of the second week. No complaints were received from any man after the forty-fifth day. It is interesting that there is no correlation between the number of men complaining of systemic symptoms and the severity of the skin burns. Characteristically, the latter developed slowly, and in the vapour cases did not reach their maximal development until, on the average, 11 days after exposure. This time appeared to be independent of the severity of the lesions (Sinclair, unpublished work,

1944) The time taken by the liquid burns to attain their maximum varied considerably, but in general was somewhat shorter. Considering the group as a whole, there was a steady rise in the extent and severity of the skin lesions

FIG 1—Distribution of systemic poisoning in time

until the eleventh day, whereas during this time there was a steady fall in the number of systemic symptoms recorded

#### Symptoms and Signs

Table I sets out the various symptoms observed in this series. It is evident that most of them might be produced by any state of general intoxication, and are not in any way

TABLE I—Relative Incidence of Symptoms

Symptom	Vapour Cases		Liquid Cases		All Cases	
	No of Men Com-plain- ing	Percentage Com-plain- ing (out of 86)	No of Men Com-plain- ing	Percentage Com-plain- ing (out of 16)	No of Men Com-plain- ing	Percentage Com-plain- ing (out of 102)
Nausea	50	58	11	69	61	60
Headache	36	42	6	38	42	41

Total no com-plain- ing of one or more symp- toms	86		16		102	

peculiar to mustard-gas poisoning. Two rather more unusual signs—tremor and tachypnoea—were restricted to severely burned cases. Table I also shows, for each symptom, the percentage of the total number exhibiting systemic symptoms who complained of that symptom. It

will be seen that there is a striking agreement in these percentage figures between the vapour and the liquid cases, thereby indicating that the overall clinical picture of each group of men was similar in spite of the differences in the type of skin lesion and its mode of production.

The clinical picture of systemic poisoning showed, nevertheless, a considerable variation with time. Table II

TABLE II—Distribution of Individual Symptoms in Time

Period	No. of Complaints of										Total
	Nausea	Vomiting	Anorexia	Abdominal Pain	Headache	Lassitude	Insomnia	Tachypnoea	Diarrhoea	Vertigo	Tremor
First day	41	10	3	3	18	12	4	5	1	4	6
Remainder of first week	82	7	17	18	37	47	53	—	11	1	9

Third week	2	—	14	2	3	1	—	—	—	—	7
Fourth week	5	—	12	15	6	—	—	—	1	—	7
Fifth week	—	—	7	7	—	—	—	—	—	—	7
Later than fifth week	—	—	—	—	—	—	—	—	—	—	10
Total	145	24	70	59	76	71	81	5	16	6	53

shows the number of complaints made of each symptom during different periods after exposure. A consideration of this table shows, for example, that on the day after exposure nausea and vomiting between them accounted for 47.7% of the total number of complaints made on that day, whereas complaints of anorexia and abdominal pain taken together accounted for only 5.6% of this total. Thereafter, however, there is a gradual decrease in the proportion of complaints due to nausea and vomiting, while the proportion due to anorexia and abdominal pain steadily rises with time. Other symptoms show proportional changes which are less striking. Thus the percentage of total complaints due to headache remains fairly constant, and complaints of lassitude and insomnia are practically restricted to the first two weeks.

It may therefore be said that in the first week following exposure the most characteristic complaint was of nausea with or without vomiting, whereas after the beginning of the third week anorexia and abdominal pain accounted for the greater part of the complaints made.

To evaluate the relative frequency with which any given symptom "presented," a simple marking system was adopted. One mark was allotted to each man, and if there was only one presenting symptom the whole mark was entered under this symptom. If several symptoms presented simultaneously the mark was split proportionately between them. By this procedure it was found that nausea with or without vomiting was the commonest presenting symptom, receiving 38.3 marks. Headache and lassitude each received 22.8 marks, and all the other symptoms together accounted for the remaining 18.1 marks.

#### Individual Symptoms and Signs

**Nausea and Vomiting**—Of all the symptoms which have been recorded in man after exposure to mustard gas nausea and vomiting are the commonest (Norris, 1918, Moorhead, 1919, Wilson and Mackintosh, 1920, Soltau and Elliott, 1923, Aitken, 1943, and others). Vomiting is also frequent in experimental animals (Lynch *et al.*, 1918, Warthin and Weller, 1918, Smith, 1943). It has already been noted that nausea was the commonest individual symptom of the present series. A characteristic feature of the nausea was the occurrence of intermissions. Thus one man was nauseated on the first day, and then had no symptoms of any kind until the sixth day, when he had an attack of

severe nausea lasting four days. The onset of this attack preceded by two days a generalized outbreak of vesication. The complaints of nausea recorded in Table II in the fourth week after exposure were received from a group of men exhibiting abdominal symptoms in whom nausea accompanied the other complaints.

Vomiting was always preceded and accompanied by nausea. In the worst case there was repeated vomiting and retching over a period of 48 hours. It will be noted that in Table II vomiting is recorded several times during the second week. The circumstances of such delayed vomiting were carefully examined, but it was necessarily difficult to exclude factors other than the effects of mustard. It is possible that in some instances the vomiting may have a partly functional origin (Wilson and Mackintosh, 1920, Soltau and Elliott, 1923).

**Headache**—Headache of the type described by Moorhead (1919), Soltau and Elliott (1923), and Aitken (1943) was a feature of many cases. It was characteristically frontal, continuous rather than remittent, resistant to medication, and of a peculiarly unpleasant nature. In some of the worst cases headache was responsible for a considerable amount of disability. For example, one man complained of intense headache from the first to the third day, sufficient to make him cry out and to necessitate his admission to hospital on the fourth day. The headache disappeared on the seventh day, but from then until the fifteenth day intermittent nausea, vomiting, vertigo, insomnia, and anorexia were present. On the twenty-first day the headache reappeared in an even more severe form than before, and lasted until the twenty-seventh day. This man suffered from mustard burns which were only moderate in degree, but it was necessary to retain him in hospital solely because of his systemic manifestations. It is probable that he represents an unusual degree of sensitivity to mustard-gas poisoning.

**Lassitude**—Lassitude has been noted as a feature of mustard cases by Moorhead (1919), Wilson and Mackintosh (1920), and Aitken (1943). In the severe cases in this series the men were most unwilling to do anything more in their spare time than lie down and try to sleep. This finding has the more weight since it was recorded on Australian fighting troops in the absence of pain or severe burns. It might be expected that the occurrence of lassitude would run parallel to that of insomnia, but in only 12 of the men were lassitude and insomnia both present, and in only 5 of these were the two symptoms recorded simultaneously. It is evident, therefore, that the lassitude could not be attributed solely to loss of sleep.

**Insomnia**—Before attributing insomnia to the specific action of mustard gas it is necessary to exclude the factors of pain, irritation, or itching arising from the skin burns. It is probably for this reason that insomnia has rarely been mentioned as a symptom of mustard poisoning (von den Velden, 1921). Nevertheless, in their initial stages mustard burns are relatively painless (Soltau and Elliott, 1923). In 12 of the 16 more severely affected men the onset of insomnia occurred before the third day, and it is noteworthy that none of these men advanced the reason of discomfort as the cause of his complaint. It is possible, however, that insomnia occurring later was, at least in part due to pain or irritation.

**Anorexia and Abdominal Pain**—Reference to Table II shows that complaints of loss of appetite occurred not only in the first few days, as might perhaps be expected in any series of skin burns, but also as late as the fourth and fifth weeks after exposure. At the beginning of the fourth week a condition supervened in 4 men which was char-

acterized by anorexia, abdominal pain, and occasional nausea. Abdominal pain was also recorded in the early stages (Table II), but was usually not so severe as in the delayed cases. In the literature epigastric pain appears frequently as an early and acute symptom of mustard-gas poisoning (Mandel and Gibson, 1917, Moorhead, 1919, Soltau and Elliott, 1923, Chiesman, 1944), but its occurrence in the later stages does not appear to have been mentioned. Hobbs (1944) has described ulceration of the duodenum in a fatal case of mustard-gas poisoning, and the nature of the delayed pain observed in this series is of interest in this connexion. It occurred from half an hour to an hour and a half after meals, and lasted for a few hours. It was usually a steady ache, situated in the epigastrium and accompanied by a diffuse epigastric tenderness. It was not relieved by food, but could be alleviated by alkali, it did not interfere with sleep. Flatulence and heartburn were not observed, and the pain bore no relation to the type of food consumed.

**Diarrhoea**—Diarrhoea was in all cases mild and of short duration. Both Soltau and Elliott (1923) and Wilson and Mackintosh (1920) are emphatic that diarrhoea in gassed cases in the 1914-18 war was due to associated conditions rather than to mustard-gas poisoning. Moorhead (1919) mentions diarrhoea of a dysenteric type, but states that constipation was the rule. Nevertheless, diarrhoea is a prominent feature in experimental animals (Lynch *et al.*, 1918, Smith, 1943), and it has been regarded as a leading symptom of systemic intoxication by mustard gas (Smith, 1943). In this series detailed records were not kept of controls, but it may be said that diarrhoea was certainly not more common in the volunteers than in the camp staff, who were living and working under similar conditions.

**Tremor**—The occurrence of tremor has been described in experimental animals following the intravenous injection of mustard gas (Warthin and Weller, 1918), but, except for one case mentioned by Wilson and Mackintosh (1920), does not appear to have been particularly noted in man. In this series it was restricted to severely burned men, in whom it appeared within a few hours of exposure. In all the vapour cases affected it involved the whole body, especially the hands, and at its worst resembled well-marked shivering. The men did not, however, complain of feeling cold and the body temperature was in all cases normal. The tremor was coarse and showed frequent remissions, it was not under voluntary control. The deep reflexes were invariably exaggerated, but examination of the central nervous system disclosed no other abnormalities. In all cases the tremor disappeared within 48 hours. In one man with liquid burns an exactly similar tremor was noted on the second day after exposure. In another a coarse tremor of the hands and fingers was present throughout his stay in hospital (45 days). This man had severe multiple third degree burns in 30 distinct areas. These areas were such as to preclude any testing of the usual deep reflexes in either legs or arms. He was, however, extremely unsteady and incoordinated. He became nervous and excitable, and his mental condition during the first few weeks approximated to an anxiety state. Examination of the central nervous system was negative, and by the time his burns had healed adequately the deep reflexes were normal.

**Vertigo**—Vertigo has been noted by Aitken (1943) in vapour cases, and was present in six vapour cases in this series. It did not occur apart from nausea, and never lasted longer than one day.

**Tachypnoea**—In four of the five vapour cases "tremor" tachypnoea began within a few hours, at the same time as erythema appeared. Nine hours after exposure the resting recumbent respiratory rate had risen in all four to 30 per minute or over, and in one case to 40 per minute.

Breathing was in all cases shallow and fairly regular, and there was no evidence of dyspnoea. Twenty-four hours after exposure there was no disturbance of respiration in any man.

One of the men severely burned by liquid also complained of considerable "breathlessness" during the first 24 hours, even while lying in bed. It is interesting to note that an increased respiratory rate has been reported in goats following the contamination of the skin by 40–50 mg/kg of liquid mustard (Allen, Cameron, Coles, and Rutland, unpublished work, 1944). These authors state that the respiratory rate "may reach high levels between the sixth and twelfth hours." Similar results were reported by Lynch *et al* (1918) in dogs. It is therefore probable that the tachypnoea seen in human cases is due to a direct action of absorbed mustard derivatives rather than to any non-specific cause connected with skin damage. Both Mandel and Gibson (1917) and Norris (1918) mention rapid breathing as an early symptom in mustard-gas casualties, but in the men they describe it is apparent that protection of the respiratory tract was inadequate, and that the rapid breathing was the first sign of bronchitis. Moorhead (1919) and Aitken (1943) note the occurrence of pain in the chest, probably from the same cause.

**Anxiety State**—Reference has already been made to the occurrence of a well-marked anxiety state in one of those severely burned by liquid mustard. Two other men, both badly burned, showed a very similar condition for the first two weeks after exposure. All three were "jumpy," irritable, and restless, and were afraid that they were going to die. In all cases recovery was rapid once the lesions had demonstrably started to heal. These men presented a marked contrast to the tired listlessness characteristic of many others in this series. Restlessness and irritability are described by von den Velden (1921), while Wilson and Mackintosh (1920) mention a case in which "mental excitement" was prominent.

**Temperature Pulse Blood Pressure**—Cases of marked toxæmia were sometimes accompanied by an irregularly raised temperature, which did not exceed 101° F (38.3° C). This was not associated with sepsis, which was very uncommon in this series. The pulse rate in such men was correspondingly increased. Elevation of the pulse rate on the first day usually appeared to be due to the effort of retching.

In Moorhead's series (1919) the blood pressure was often low, while in Aitken's cases it was slightly raised. In four cases of liquid poisoning in this series there were signs of surgical shock, accompanied by evidence of haemoconcentration and a rise in the blood non-protein nitrogen, but in none of these could the blood pressure be satisfactorily taken owing to the position of the burns on the arms and thighs.

#### Clinical Pathology

One of the most characteristic effects of severe intoxication by mustard gas is a gradual fall in the number of circulating leucocytes, with concomitant changes in the bone marrow (Needham, Cohen, and Barrett, 1947). In fatal cases a condition amounting to aleukaemia may precede death (Hobbs, 1944). In none of the men in this series was there any definite evidence of a leucopenia, but in some of the severely burned cases there was a statistically significant temporary fall in the ratio of neutrophil polymorphs to lymphocytes. A polymorphonuclear leucocytosis, attributable to the presence of raw skin surfaces, occurred in many cases of vapour poisoning about the end of the first week and lasted for about ten days.

Moorhead (1919) observed that in mustard-gas poisoning the coagulation time of the blood was often markedly

FIG 2—Effect on blood coagulation time. The course of the mean blood coagulation time in 10 men exposed to mustard vapour. The day of exposure is indicated by an arrow, the limits of the pre-exposure values by interrupted lines, and the mean pre-exposure value by a continuous line. Points on the graph showing statistically significant departures from this mean are circled.

decreased. This observation was confirmed in a number of vapour and liquid cases in this series. Fig 2 shows the course of the mean coagulation time for a group of ten men exposed to mustard vapour. It was unfortunately not possible to investigate the cause of this rapid coagulation of the blood.

In view of the occurrence of "abdominal" symptoms, and of the known association of peptic ulcers with mustard-gas burns (Hobbs, 1944), an investigation of the total and free acidity of the gastric contents was carried out by Thompson (unpublished work, 1945) on a number of men in this series. He concluded that "under the conditions prevailing exposure to mustard gas gives rise, in a proportion of cases, to a significant increase in the secretion of acid by the gastric mucosa." The rise in acidity was not immediate, and the maximum figures tended to occur about the eleventh day. No investigations on the gastric acidity of the men complaining of abdominal symptoms in the fourth week were carried out.

Even in the most severely burned men in this series no abnormal changes could be demonstrated in the sedimentation rate, the platelet count, or the composition of the urine.

#### Discussion

Lynch *et al* (1918) were among the first to suggest that many of the symptoms observed in men gassed by mustard were due to the action of mustard gas as a specific systemic poison. At the time it was believed by many that the effects were caused solely by the local tissue damage. Thus Soltau and Elliott (1923) state that "vomiting is due to the swallowing of saliva or nasal secretion which has been infected by mustard gas"—an explanation which was also accepted by Aitken (1943). Warthin and Weller in 1918 found "no evidence of any systemic poisoning by the absorption of dichlorethyl sulphide from the skin, eyes, or mucous membranes of the respiratory or gastro-intestinal tracts." Subsequent work, however, has left no doubt that mustard gas has a specific toxicity, manifested particularly by its effect on the haemopoietic tissues, irrespective of the route by which it is administered (Smith, 1943).

In 1943 work on the exposure of human volunteers in Australia showed that severe systemic symptoms could be produced despite the fact that fully effective respirators were worn throughout exposure. This condition also applies to all the cases reported in this paper, with the exception of five of the men exposed to liquid contamination, who wore eye-shields instead of respirators. The only possible channel of entry for mustard derivatives into the body was thus the intact skin. It follows that the symptoms and pathological changes observed can only be due either to the action of derivatives of mustard circulating in the blood after having been absorbed through the skin or to the absorption of non-specific metabolites from the damaged skin.

The latter explanation cannot be wholly neglected. Gibson and Brown (1944), reporting on shock following thermal burns, state that vomiting was frequent and often severe. Further, many of the symptoms occurring in the cases exposed to mustard are, by reason of their general character, difficult to attribute solely to the action of mustard derivatives. Nevertheless it is probable that the observed picture is for the most part due to this cause, for several reasons.

1 It has been shown that the systemic symptoms in experimental animals exposed to mustard vapour or to liquid skin contamination can be almost exactly reproduced by the intravenous injection of pure mustard or derivatives of mustard (Smith, 1943).

2 In this series the symptomatology of vapour and liquid cases was exactly similar in spite of the marked differences in the type of skin burn produced.

3 In the present series 65% of the men affected became so within 24 hours, and in very few of these was the degree of skin damage greater than an erythema by the end of this time. Indeed, in some cases the onset of nausea preceded the appearance of erythema. It is thus difficult to explain the symptoms solely on the basis of the liberation of toxic metabolites by skin damage. Further, in the group as a whole the severity of the skin lesions showed a progressive increase until the eleventh day, whereas during this time the number of systemic symptoms steadily fell.

4 The leucopenia characteristic of severe poisoning by mustard gas, however administered, is not produced by other, non specific, substances injurious to tissues.

It is reasonable, therefore, to regard most of the findings in these men as being due to the specific action of mustard. There is one group of symptoms, however, which may be in part due to a non-specific mechanism. Peptic ulcer is a well-recognized complication of thermal burns (Harkins, 1938), and it seems possible that the association of abdominal pain, anorexia, and nausea which occurred in a few of the men during the fourth week after exposure was in some way related to the skin damage rather than to mustard poisoning. The number of cases examined by Thompson (1945) is too small to show any definite relation between symptoms referable to the gastro-intestinal tract and the appearance of hyperacidity, but the findings merit further investigation.

The mechanism by which the mustard derivatives which have been found in the blood stream of experimental animals act to produce clinical manifestations is obscure, except that there is a specific toxic effect on the bone marrow (Needham, Cohen, and Barrett, 1947). It is possible that many of the apparently diverse symptoms produced in man have a common pathological origin. It must be pointed out that the results in this series show that systemic intoxication in both liquid and vapour cases occurs much more readily in the Tropics, probably owing to a generally enhanced power of the skin to absorb mustard gas (Cullumbine, 1948).

Not all the symptoms and signs observed had the same practical importance with reference to disability. In this respect the incapacitating potentialities of nausea, vomiting, and headache may be emphasized. The necessarily limited clinical pathological investigations in this series showed that, although changes in the leucocyte count and in the blood coagulation time were noted, these changes were in no instance such as to cause concern, and did not affect the clinical course of the cases.

### Summary

An account is given of the various clinical symptoms and signs encountered in 102 cases of mustard-gas poisoning observed in the Tropics.

These symptoms followed the absorption of mustard gas through the skin, and were in great part the result of a specific toxic action of mustard derivatives.

Severe systemic manifestations were produced in some instances, although the blood changes found were in all cases clinically unimportant.

The incidence of systemic symptoms was greatest on the day after exposure, and fell progressively thereafter.

The commonest individual symptom was nausea, in the more severe cases accompanied by vomiting. The possible relation of abdominal symptoms to a disturbance of gastric secretion is discussed.

Potentially incapacitating symptoms occur in the Tropics very much more readily than in temperate climates.

The kindness of the Australian Chemical Defence Board in permitting publication of the work carried out under its direction is gratefully acknowledged. Permission to publish has also been received from the Chief Scientist, Ministry of Supply.

The Board of Trade reports that the President of Finland has submitted a Bill to the Diet proposing the establishment of a Government Company for the importation and distribution of medicinal preparations on a wholesale basis. The share capital of the company is to be 100 million Finnish marks, but can be raised to 300 million Finnish marks. The Government will hold all shares with the exception of two, which could tentatively be transferred to the Public Pension Board and the Helsinki University. In the preamble to the Bill the Government states that as long as the importation and distribution of medicinal preparations are solely in the hands of profit-seeking private companies there is always the danger that prices will be too high. It is therefore essential that the trade should also be conducted by a company whose objects are entirely confined to promoting the public welfare. As the Government company will sell the products at the lowest possible prices it will be the competing firms to make corresponding reductions in prices. The new company will also handle the distribution of products to the State and municipal hospitals.

## TREATMENT OF TYPHOID CARRIERS WITH PENICILLIN AND SULPHATHIAZOLE\*

BY

AND

S. THOMSON, MD, DPH

(From the Public Health Laboratory Service)

Chemotherapy has hitherto yielded very disappointing results in the treatment of typhoid carriers, and radical surgical treatment is by no means regularly effective. Bigger (1944, 1946) described a synergistic action of penicillin and sulphathiazole against various organisms, including *Salmonella typhi*, and Comerford, Richmond, and Kay (1946, 1947) treated two carriers with a combination of these drugs with apparent success. It was decided to treat a larger series of known chronic typhoid carriers with the same two drugs to see if the beneficial results could be regularly expected.

Experiments were carried out at the same time to determine the sensitivity of strains of *Salm typhi* to penicillin and sulphathiazole and to decide if penicillin is excreted in the bile in concentrations sufficient to influence the growth of *Salm typhi*.

### Sensitivity of Strains of *Salm typhi* to Penicillin and Sulphathiazole in vitro

The sensitivity of the strains of *Salm typhi* from the carriers to the separate and combined actions of penicillin and sulphathiazole was tested in nutrient broth treated according to the method described by Harper and Cawston (1945). One batch of culture medium was used throughout. Sixteen strains were tested—five of Vi-phage Type A, five of Type C, four of Type E1, and two of Type N (Craigie and Felix, 1947). Recently isolated cultures were maintained on Dorset's egg medium, and inocula for the *in-vitro* tests were prepared by two successive subcultures in broth at four-hourly intervals. Inocula varying from 5,000 to 1,000,000 organisms were subjected to the action of different concentrations of the drugs in 5 ml of broth. The absence of turbidity after incubation for 48 hours was recorded as evidence of inhibition. A quantitative estimate of the bactericidal effect of the drugs was then made by subculturing various quantities from the original tubes into fresh medium containing an excess of penicillinase and para-aminobenzoic acid.

The results of the *in-vitro* tests may be summarized as follows:

1. Penicillin alone in a concentration of 8 units per ml inhibited the growth for 48 hours of 11 out of 16 strains. The remaining 5 were inhibited by 16 units per ml. Complete sterilization was achieved by slightly higher concentrations, 12 strains being sterilized in 48 hours by a concentration of 16 units per ml and 4 strains by 32 units per ml. These results were more or less independent of the size of the inoculum between 5,000 and 1,000,000 organisms and of the Vi-phage type.

2. The action of sulphathiazole alone was dependent upon the size of the inoculum. With small inocula of 5,000 to 10,000 organisms 7 strains were sterilized in 48 hours by a concentration of 1.25 mg of sulphathiazole per 100 ml, 4 strains

required a concentration of 2.5 mg per 100 ml, and 5 strains 5 mg per 100 ml. An inoculum of 100,000 organisms was regularly inhibited by a concentration of 5 mg per 100 ml, but a lethal action in 48 hours was not common. With inocula of 1,000,000 organisms a concentration of 5 mg per 100 ml rarely inhibited growth.

3. When the joint action of the two drugs was examined the concentration of sulphathiazole was kept constant at 5 mg per 100 ml, the concentration of penicillin and the size of the inoculum being varied. As small inocula (5,000 to 10,000 organisms) were sterilized in 48 hours by a concentration of 5 mg of sulphathiazole per 100 ml no studies were made of any possible joint action of the two drugs. With large inocula (1,000,000 organisms) the presence of penicillin in small amounts together with 5 mg of sulphathiazole per 100 ml often inhibited growth, but a sterilizing action was seldom demonstrable. Complete sterilization of the inoculum in most cases was achieved only when the concentration of penicillin approximated to that which would bring about this effect unaided by sulphathiazole. As an approximate measure it could be stated that the presence of sulphathiazole in a concentration of 5 mg per 100 ml reduced to one-half the concentration of penicillin required to effect sterilization of an inoculum of 1,000,000 organisms.

### Penicillin in Bile

Evidence was sought that penicillin is excreted in bile in sufficient concentration to kill *Salm typhi* or at least to inhibit its growth. A tube was passed into the duodenum of a healthy subject who was receiving intramuscular injections of 500,000 units of penicillin every three hours. Ten minutes after the fourth injection a sample of bile aspirated after the administration of magnesium sulphate as a cholagogue contained more than 100 units of penicillin per ml and the Oxford staphylococcus was inhibited by a 1 in 6,000 dilution of the bile in broth. The bilirubin content of this sample was 150 mg per 100 ml. A similar examination in another person yielded a sample of bile containing more than 20 units of penicillin per ml.

A number of examinations were made of samples of bile from patients whose gall-bladders had been removed by surgical operation. In one patient a fine catheter was led into the cystic duct and left there for several days for the collection of samples of bile. After the second intramuscular injection of 500,000 units of penicillin the bile contained 25 units per ml, inhibiting the growth of the Oxford staphylococcus at a dilution of 1 in 1,280, and a concentration of 12 to 25 units was steadily maintained thereafter. A similar result was obtained in a patient whose gall-bladder was drained to relieve an empyema. Initially, this patient was given intramuscular injections of 100,000 units every three hours, and after 12 hours the fluid from the gall-bladder inhibited the growth of the Oxford staphylococcus at a dilution of 1 in 64 (approximately 1 unit), but *Salm typhi* was not inhibited. The dose of penicillin was increased to 500,000 units every three hours, and 12 hours afterwards the concentration of penicillin in the bile was between 10 and 20 units per ml. The bile inhibited the Oxford staphylococcus at a dilution of 1 in 1,000 and *Salm typhi* at a dilution of 1 in 8. In a third patient the contents of the gall-bladder excised one hour after a single intramuscular injection of 1,000,000 units of penicillin contained 12 units per ml.

There was thus evidence that penicillin is excreted in the bile in adequate concentrations to inhibit or destroy *Salm typhi* if injections of the order of 500,000 units are given at intervals of three hours.

### Therapeutic Trial

Seventeen faecal carriers of *Salm typhi* were selected for treatment. There were five carriers of Vi-phage Type A, five of Type C, four of Type E1, and three of Type N.

\*Based on a report to the Medical Research Council.

All were known to be regular excretors of *Salm typhi* as specimens of faeces had been examined in our laboratories at monthly or in some cases weekly intervals for very long periods. A single batch of yellow penicillin (Glaxo) was used for the majority of the cases, but in two who were given injections of 5 million units it was necessary to use crystalline penicillin.

Three different courses of treatment were tried, the results of these are shown in detail in the accompanying table.

*Courses of Treatment for Typhoid Carriers*

Course	Case No.	Known Duration of Carrier State	Vi phage Type	Total Dosage		Result	
				Pen (mill units)	Sulph (g)		
1	1	6 years	A	30	45	Positive	11th day

\* Cholecystectomy two years before treatment

**Course 1 Continuous 5-Day Course**—In the continuous course of treatment 1,000,000 units of penicillin were injected intramuscularly and 15 g of sulphathiazole were given orally every four hours for five days. The total course thus consisted of 30 million units of penicillin and 45 g of sulphathiazole. Seven patients were so treated. An eighth patient received 28 million units of penicillin in doses of 500,000 units every three hours for seven days and a total of 25 g of sulphathiazole. Seven of the eight cases were found to be excreting typhoid bacilli within two weeks of the end of treatment. The remaining case was found positive on the 30th day, but as the patient had left hospital a few days after the end of treatment no specimens were received between the 7th and 30th days.

**Course 2 Intermittent 21-Day Course**—The intermittent course of treatment was designed at the suggestion of Professor J W Bigger. It consisted of the same four-hourly doses of penicillin and sulphathiazole in four courses each lasting two and a half days, the individual courses being separated by intervals of two to four days. The total dosage as planned was thus 60 million units of penicillin and 90 g of sulphathiazole, but in some instances slight adjustments were necessary. The precise amounts given to the patients are shown in the table.

Eight patients received the intermittent course in the first instance. Four of these gave positive cultures within one week of the cessation of treatment, one became positive on the 28th day, and one on the 119th day. One case due to Vi phage Type N has remained negative for 48 weeks to date and represents the only apparent success in the first 16 cases treated by a single continuous or intermittent course.

After a short interval four patients were selected for a further trial by the full intermittent course. Three of them had previously had the continuous course and one the intermittent course. Two of these four patients were positive again within a week of the termination of the second course. The other two were still negative 36 weeks after the treatment. It will be seen that two of the successes were obtained in Vi-phage Type N carriers, but a third carrier of this type (almost certainly the same strain) was not cured (Case 16). Two of the cured carriers who had harboured Vi phage Type N showed a definite drop in their typhoid Vi-agglutinin titre. The Vi-agglutinin titre of the third

apparently cured carrier (Vi phage Type E1) has so far unchanged.

**Course 3 Intermittent Course with Massive Doses of Penicillin**—When the results of the above attempts were reviewed it was decided that there was little ground for optimism, and no conclusion could be reached regarding a dosage which might be expected to give encouraging results. In a final attempt two carriers were treated with injections of 5 million units of penicillin together with 15 g of sulphathiazole orally every three hours for 24 hours, the total daily dosage being 40 million units of penicillin and 12 g of sulphathiazole. The patients were so treated on three occasions, separated by rest intervals of three days. Each carrier therefore received a total of 120 million units of penicillin and 36 g of sulphathiazole. One of these cases had been previously treated by the ordinary intermittent course of 21 days (Case 13 of the series), but the other had not previously been treated by penicillin or sulphathiazole. Both patients remained positive, and excretion of typhoid bacilli did not cease even temporarily.

*In-vitro* tests with the carrier strains isolated before and after treatment showed that they had not altered their resistance to penicillin and sulphathiazole.

### Summary and Conclusions

Attempts were made to clear 17 chronic typhoid carriers of infection. At first eight cases were given a continuous course of treatment similar to that employed successfully by Comerford *et al* (1946) in two cases. All eight cases resumed excreting typhoid bacilli soon after the end of the course of treatment.

When it became apparent that the continuous treatment was not as effective as had been hoped it was decided to try an intermittent course suggested by the work of Bigger (1944) as a method of eliminating 'persisters'. Accordingly much larger amounts of both drugs were given over a period of 21 days with rest intervals, and in eight cases there was one apparent success. Soon afterwards four of the unsuccessfully treated cases were selected for a further trial by this method, with two more apparent successes.

In order to decide if yet larger doses might succeed, two cases, one of which had been previously treated, were given 40 million units of penicillin and 12 g of sulphathiazole a day on three occasions. Both attempts were unsuccessful.

Although the results of *in-vitro* tests suggested that typhoid carriers might be cleared of infection by some combination of penicillin and sulphathiazole the results of the therapeutic trial were not encouraging. There were only three apparent successes out of 17 cases in spite of the very large amount of penicillin and sulphathiazole used.

We are indebted to the superintendents and medical staff of several hospitals and to several medical officers of health for their willing co-operation in making this trial. We are grateful to Dr A Felix FRS, for much co-operation and helpful criticism of this work.

Seven holders of United Nations Social Affairs Fellowships from Greece, India, the Philippines, and Poland arrived in London on July 19 to spend from three to six months in Britain on course of study arranged by the British Council. Social Affairs Fellowships are awarded to those directly concerned in work of reconstruction and rehabilitation. Typical subjects of study are welfare in industry, child welfare, social aspects of tuberculosis, and juvenile delinquency. Lectures are being given on such subjects as health services, rehabilitation and resettlement of the disabled, the organization of welfare in industry, employment exchange services, the work of a borough council, the Education Act of 1944, housing management, town planning in London, administration of justice, delinquency, probation, and social security. Visits will be made to the House of Parliament, County Hall, St Helier's Hospital, Carshalton, an employment exchange, the Minerva Housing Estate, Bethnal Green and a meeting of Holborn Borough Council.

## PARATYPHOID OSTEOMYELITIS

## REPORT OF TWO CASES

BY

RACHMIEL ROZANSKY, M.D.

E N EHRENFELD, M.D.

AND

Y MATOTH, M.D.

(From the Department of Bacteriology and Serology,  
Medicine B, and Paediatrics B of the Hadassah-Rothschild  
University Hospital, Jerusalem)

Paratyphoid osteomyelitis is uncommon. We found only 21 cases recorded in the literature at our disposal. The following two case reports present some interesting features: the first patient was an infant, and in the second case there was an unusually long period between the initial infection and the appearance of the osteomyelitis.

## Case 1

A female infant aged 1 year was seen at the out-patient department on Feb. 19, 1947. The mother reported that the child had been feverish for three weeks, although the temperature had not been taken. On examination a tender swelling of the left shoulder was found and a preliminary diagnosis of osteomyelitis was made. The following day the child was admitted to the paediatric department. The past history was not significant.

Examination showed a well-developed child in a fair state of nutrition, with a temperature of  $37.5^{\circ}\text{C}$  ( $99.6^{\circ}\text{F}$ ) on admission. The liver was felt three fingerbreadths and the spleen one and a half fingerbreadths below the costal margins. Over the left acromio-clavicular region a soft swelling the size of a walnut was noted. The skin over the swollen area showed increased venous markings and fluctuated on palpation. The temperature of the affected area did not seem higher than that of the surrounding skin. No other abnormal findings were discovered on physical examination. The blood count on Feb. 21 was: 3,400,000 erythrocytes, 19,400 leucocytes (neutrophils 34%, monocytes 2%, lymphocytes 58%, band forms 6%, no eosinophils). Routine urine examination was negative.

The diagnosis of osteomyelitis was confirmed by radiograph, and penicillin treatment was started (60,000 units daily). Aspiration of the swelling on Feb. 21 yielded 2 ml of red-streaked pus, a direct smear of which showed Gram-negative rods. Culture of the pus on MacConkey's medium produced a fine growth of non-lactose-fermenting colonies of a motile Gram-negative bacillus. By the usual routine sugar reactions and an agglutination test the organism was identified as *Salm paratyphi B* (Schottmuller). A second aspiration five days later again yielded a pure culture of *Salm paratyphi B*. This was also isolated from the urine and faeces. On Feb. 25 a blood culture was negative and a Widal test showed paratyphic B 1 in 500. Agglutination of the serum with own strain was positive at 1 in 5,000.

Penicillin treatment had no apparent influence on the course of the disease, and in view of the bacteriological findings it was discontinued. The further clinical course was uneventful, the swelling gradually decreased and 12 days after admission the child was discharged from hospital, but remained under observation. In a few weeks she made a complete recovery, confirmed by radiographs and by function of the affected shoulder.

## Case 2

The patient was a 48-year-old man born in Turkey. At the age of 15 he fell from a height and injured his loin. One year later he suffered from enteric fever, which lasted about 10 weeks. During convalescence from this disease he began to suffer from pains in his thighs and loins, which became so severe that he was unable to move. His physician told him that he was suffering from "coxalgia" and he was put in plaster for six months. After removal of the plaster he felt well and there was no restriction of movement in the affected joints. Since that time he had always been in good health,

except for pneumonia 12 years ago, from which he recovered without any complications.

The patient was operated upon for bilateral inguinal hernia in August, 1946. A few weeks later he began to feel pains in his thighs and loins. At the same time his temperature became subfebrile ( $37.5$ – $38.5^{\circ}\text{C}$ ). The pain and fever lasted for three weeks, and he received penicillin treatment for 10 days in another hospital without result. On Oct. 18 he was admitted to the medical department of this hospital.

On examination he appeared pale and chronically ill. The only definite abnormal physical sign was a pronounced tenderness in the right loin and in the right hypogastric region. The temperature was  $37.5^{\circ}\text{C}$ , the pulse 100, the blood pressure 110/60 mm Hg. There were no other abnormal physical signs. Laboratory examination showed: urine, no sugar or albumin, deposit, nothing of importance, blood urea, 21 mg per 100 ml, sugar, 89 mg per 100 ml, Kahn test, negative, erythrocytes, 4,550,000, Hb 75% (Sahli), leucocytes 17,000 (neutrophils 71%, monocytes 3%, lymphocytes 23%, band forms 2%, eosinophils 1%), ESR (Linzenmeier), 40 minutes, Weltman coagulation band, 3. Radiographs of the gastrointestinal tract, chest, and urinary tract showed nothing abnormal. Blood culture and agglutination test for brucellosis were negative. Widal test showed 1 in 200 for *Salm paratyphi B* only. A radiograph of the lumbar spine showed union of the bodies of the third and fourth lumbar vertebrae.

In view of the marked tenderness in the right loin, the persistent temperature ( $37.5$ – $39^{\circ}\text{C}$ ), the rapid sedimentation rate, and the shift of the Weltman band to the left the possibility of a perinephric abscess was considered. An exploration of the perirenal tissues was made by Dr E. Joseph on Oct. 29, but no pus was found. After the operation the temperature

The intervertebral disk between the third and fourth lumbar vertebrae is almost destroyed. Synostosis between these two vertebrae. In the region of the intervertebral space a cavity is seen towards which a fistula leads from the right loin.

fell to normal and there was some improvement in the general condition, although the blood sedimentation rate remained high. A fortnight after the operation the patient was discharged.

The following day a sudden rise of temperature occurred and the pain in the right loin reappeared. Two days later he was readmitted to hospital. Examination then revealed a hot well-defined swelling below the scar of the recent operation. This swelling was tender to the slightest pressure. A superficial incision (Dr E. Joseph) yielded a large amount of pus. On

microscopical examination Gram-negative rods were seen, and on culture the isolated organism proved to possess the biochemical and serological properties of *Salm paratyphi B* (Schottmuller). The same organism was isolated from another specimen of pus taken a few days later. The patient's serum agglutinated the organism isolated from his pus at a titre as high as 1 in 5,000. Urine and faeces yielded no growth of *Salmonella*. After the operation the temperature dropped, the ESR became less rapid, and the patient greatly improved. When he was discharged from hospital on Dec 12 the incision wound had almost healed. He reported back to the out-patient department a few weeks later complaining of pain in the right loin and renewed fever in the evenings. Into a small opening which remained in the incision scar lipiodol was injected, and an x-ray film showed communication with a cavity which tomography revealed between the third and fourth lumbar vertebrae (see illustration). Since then the patient has been seen repeatedly. When the fistula stops discharging the pain and fever reappear, but cease when drainage is re-established.

### Comment

According to various statistics, almost 1% of cases of typhoid are complicated by osteomyelitis. 0.82% according to Winslow (1923), 0.87% according to Keith and Keith (1926). The reported incidence of this complication in cases of paratyphoid is much lower. Webb-Johnson (1917) saw only two instances of bone involvement in 1,038 cases of paratyphoid. Winslow (1924) in 100 cases of paratyphoid observed no case of osteomyelitis. Ross Veal and McFetridge (1934) collected 16 cases from the literature and added two of their own. Their series does not include the cases of Reenstjerna (1910). Two additional cases have since been reported (Just, 1937, Jetter, 1938). Our two cases bring the total number recorded up to 23. From the historical point of view it is interesting to recall that *Salm paratyphi B* was first isolated—even before its definite identification by Schottmuller—from an osteomyelitic lesion of the sternoclavicular region by Achard and Bensaude (1896).

Osteomyelitis, both typhoid and paratyphoid, is rare in children. Winslow (1923), who collected all bacteriologically proved cases, found only four cases between the ages of 2 and 10. A typhoid abscess of the spine in a 3-year-old child was reported by Abbassy (1946). We were unable to find in the literature an instance of typhoid or paratyphoid bone abscess in infants. Our case of paratyphoid osteomyelitis in a 1-year-old infant seems to be the youngest recorded.

In Case 2 the abscess presented itself clinically 32 years after an attack of enteric fever. The coxalgia for which the patient at that time was put in plaster was apparently a paratyphoid spondylitis. The localization in our patient was typical, as the lumbar spine is involved in about 70% of cases showing spine lesions (Ross Veal, 1939).

The affinity of the typhoid and paratyphoid bacilli for the bone marrow invites consideration. The bacillus is already found in the bone marrow at the beginning of the infection (Storti and Filippi (1937). There is also good clinical and experimental evidence to show that the bacillus may persist in the marrow for a very long time (Dmochowski and Janowski, 1895; Ludke, 1909; Coplans, 1936; Ling *et al*, 1940; MacDonald, 1941; Kernwein and Capps, 1943).

Ten cases of typhoid osteomyelitis have been reported in the literature in which the time interval between disease and the bone complication exceeded ten years. We found only one case of paratyphoid osteomyelitis reported in which the bone abscess appeared 20 years after the original disease (Jensen and Kock, 1913).

What are the factors involved in the sudden exacerbation of an infection after so long a latent period? Most

authors agree that trauma may upset the equilibrium between the bacilli and the defence mechanism of the body. The traumatic agent need not be a direct blow. Undue strain or fatigue, pyrexia, or anything likely to lower the body's capacity for defence may cause the latent infection to flare up and show itself clinically. In our case the herniotomy may well have acted as such a trigger mechanism.

### Summary

Two cases of paratyphoid osteomyelitis are reported, one occurring in a 1-year-old infant and the other in an adult 32 years after the initial infection.

Factors contributing to abscess formation and the incidence of this complication are discussed.

We are indebted to Dr J Gurevitch, head of the department of bacteriology and serology, and to Dr A Druckmann, head of the x-ray institute of our hospital, for their help.

## SALM. ORANIENBURG SEPTICAEMIA

### REPORT OF A FURTHER CASE

BY

C. N. PARTINGTON, MB, BCh

Assistant Pathologist County of Dorset

AND

T. V. COOPER, MB, BS

County Pathologist Dorset

In the first recorded case of *Salmonella oranienburg* blood infection in Britain the source of the infection was never discovered (Kerrin, Elder, and Smith, 1935). In the light of events in the recent war, when *Salm oranienburg* contamination of transatlantic dried egg was shown to be common, this original infection may well have been imported, for in 1935 food flowed in plenty to this country from all over the world.

A subsequent case was reported by one of us (Cooper, 1944), but, although intestinal infections with this *Salmonella* are not uncommon, blood infection has rarely come to light. For this reason we venture to publish a further case met with in this laboratory. There were strong reasons for suspecting dried-egg infection as the cause of the 1944 case but at that time it was ruled impolitic to say so. In our present case no history of dried-egg consumption could be obtained, but presumably this substance is an ingredient of a variety of creams and sauces which may be consumed in hotels and restaurants. The old view that the cause state was rare in salmonella infections is no longer tenable. Our present patient was shown to be a convalescent for over five weeks. Food-borne infections of this origin are therefore probable.

## Case History

The patient, an unmarried woman aged 21, was first seen by her doctor on Aug 22, 1947, having returned on Aug 19 from a holiday in Jersey, where she spent Aug 16 in bed with headache, diarrhoea, and vomiting. The headache had persisted, and the doctor's view on the 22nd was that the patient was clinically likely to be suffering from typhoid fever. Next day he therefore requested the county laboratory to undertake a blood culture. At that time the patient's bowels were constipated. Pyrexia, lassitude, and headache persisted for a further nine days. There was no rash and the spleen was never palpable. The temperature chart is here shown, the pulse was

Temperature chart of case

of the order of 70 to 80 throughout. The headache, associated as it was with stiffness of the neck muscles and the incidence of an outbreak of poliomyelitis at the time, brought in the exclusion of that condition as a further problem. There was no history of the patient having had dried egg in a form she was able to recognize, but she had partaken of salad dressings while on holiday.

We withdrew 20 ml of blood. 5 ml was put into 100 ml of bile-salt broth, 5 ml into 100 ml of glucose-proteose peptone No 3 which contained 'liquoid' and para-aminobenzoic acid, 5 ml into Wintrobe mixture, and 5 ml of clotted blood was used for the Widal test. Growth appeared in the glucose-proteose after 48 hours' incubation. No growth appeared in the bile-salt broth. Subculture produced a non-lactose fermenting Gram-negative bacillus which was motile and grew freely in taurocholate media.

Acid and gas developed in glucose, maltose, mannite, and dulcitol—all within 24 hours. There was no reaction in lactose saccharose, or salicin, but a slight acid reaction in litmus milk. The indole test was negative. Gelatin was not liquefied.

Agglutination reactions: polyvalent *Salmonella A* negative, polyvalent *Salmonella B* negative, polyvalent *Salmonella C* positive titre 1 in 250, paratyphosum C "O," positive titre 1 in 50. An organism isolated from the stools on Aug 23, 24, 30, and Sept 5 and 29 produced identical results. The first negative result was obtained on Oct 25, and all three subsequent stools were negative. The organisms recovered from the blood and faeces were confirmed by Dr Joan Taylor as conforming to *Salin oranienburg*.

A blood count on Aug 23 showed: haemoglobin, 92%, red cells, 4,630,000, leucocytes, 6,600 (polymorphs, neutrophils 70%, monocytes 4%, lymphocytes 26%). Urine taken on Aug 23 was negative biochemically and bacteriologically. Widal reactions were negative.

## Discussion

Kerrin *et al* (1935) give a similar clinical story of their case, but hypostatic pneumonia and death occurred. Their blood culture was positive in taurocholate media. Cooper's (1944) patient presented as a case of gastro-enteritis with continuing pyrexia. This case also continued to excrete the organisms for at least 55 days. In our own case it is reasonable to suppose that infectivity of the faeces ceased midway between Sept 29 and Oct 25—about 40 to 50 days after the organism was first detected on Aug. 23.

## Summary

A further example of the isolation of *Salin oranienburg* from blood is recorded.

The value of blood culture in cases of pyrexia of unknown origin is re-emphasized.

The discovery by the same laboratory of two cases of blood infection with this organism draws attention to the occurrence of septicaemia in at least a proportion of salmonella infections.

## Medical Memoranda

## Nitrogen Mustard in Polycythaemia Vera

Since Wilkinson and Fletcher (1947) reported the results of treatment of three cases of polycythaemia vera with nitrogen mustard the opportunity for treating a further case has occurred.

## CASE REPORT

The patient, a woman aged 51, had been a known sufferer from this condition since she had been admitted under the care of Professor Nattrass in 1935. At that time she complained of high facial colouring of four years' duration, with pain in the left side and nausea, dyspnoea, and palpitation of two years' duration. The haemoglobin was 106% (Haldane), the red blood cells

numbered 7,910,000 per cmm and the white blood cells 12,000 per cmm. The spleen was palpable 2 in (5 cm) below the left costal margin. No treatment was then given. In December, 1947, she again reported, stating that although the nausea had disappeared she had increased pain in the left side of the abdomen for six years, and during the last year the palpitation and dyspnoea on exertion had been more marked. Infrequent fainting attacks had also occurred. No cardiovascular abnormality was detected and the blood pressure was 150/90. The spleen was now palpable 10 in (25 cm) below the left costal margin. The haematological state is shown in the accompanying charts. It is noteworthy that though the haemoglobin and red cells had remained virtually unchanged over the last 12 years the white cells had risen from 12,000 to 36,000 per cmm.

The patient was given methyl bis(β-chlorethyl)amine hydrochloride intravenously in doses of 0.1 mg per kg of body weight on the 3rd, 8th, 19th, 23rd, 28th, 37th, 43rd, 57th, and 64th days after coming under observation. Apart from nausea and vomiting, which came on three hours after each injection and lasted for two to three hours, no untoward side effects of the treatment were encountered. As will be seen from the charts, the haemoglobin level and the red and the white blood cell counts dropped during the first month and thereafter there was a pronounced tendency for these values to increase in spite of treatment. There was no significant alteration in the size of the spleen during the three months period of observation. The patient stated that she experienced slight alleviation of her symptoms during the first two months.

This case falls into line with two of the three cases of polycythaemia vera in Wilkinson's series in which the therapeutic response to nitrogen mustard was unsatisfactory.

I wish to thank Professor Nattrass, Royal Victoria Infirmary, Newcastle upon Tyne, for permission to publish this case, and Dr W. A. R. Thomson, of Boots Pure Drug Co., Ltd., for the supplies of nitrogen mustard.

A. W. WOODRUFF M.D., M.R.C.P., D.T.M. & H.

## Reviews

### VISIBLE SPEECH

*Visible Speech* By Ralph K Potter, George A Kopp, and Harriet C Green (Pp 441 illustrated £1 5s) New York D Van Nostrand Company, Inc London Macmillan and Co 1947

An important and indeed almost Utopian project has been launched successfully. The research workers at the Bell Telephone Laboratories show in this book how a machine can translate the sounds of speech into patterns which the eye can learn to interpret. A startling principle has been proved, and the imagination is roused by the possibilities which this opens up. The authors wisely do not exploit this emotional appeal, instead they describe in a careful and matter-of-fact way what has been achieved, how it was done, and how much more work will be required before the implications can be fully understood.

"Visible speech" as described in this book is a representation of sound according to frequency, intensity, and time. That such a representation could retain all the intelligence contained in the sound has long been appreciated, it is in fact similar to the analysis presumed to take place in the inner ear. But what is new is the experimental proof that the visual representation can be learnt and interpreted. Some experimenters have achieved considerable competence in this, and the authors give illustrations and a carefully devised commentary to enable the reader to learn the first steps for himself. The reader can thus obtain a clear idea of the processes of learning this new symbolism and assess the difficulties involved.

The authors discuss the possible application of this type of technique to problems of deafness, and these suggestions seem to promise much. Teaching the deaf has always been an arduous task, and this work may well become the foundation of an entirely new method. Though little work with the deaf is yet on record the authors mention the case of one congenitally deaf man who learnt by this technique to use a telephone. An extension of the technique may even result in the portable "translator" as a permanent aid for the deaf, but the technical problems involved are evidently still very great. The authors discuss other applications of the technique covering nearly all fields of sound analysis, linguistic and phonetic investigations, the study of animal calls, the suppression of mechanical noises, and numerous other problems may all benefit. A precise and permanent record that can be investigated at leisure may well provide a better means of classifying and analysing sounds than the rapid and subjective judgment made by listening.

It is evident that the most lavish experimental technique was used to produce that form of display which held out the greatest promise. The authors point out that there is nothing final about the present method, and they refer to some variants of it. But it would have been interesting to hear why a horizontal time scale, a vertical scale for frequency, and an intensity-of-light representation of intensity of sound were chosen through out all experiments.

THOMAS GOLD

### PRINCIPLES OF SURGERY

*Introduction to Surgery* By Virginia Kneeland Frantz, M.D., and Harold Dortic Harvey, M.D. (Pp 216, illustrated 12s 6d) New York and London Geoffrey Cumberlege, Oxford University Press 1946

The last sentence in this book runs thus: "Whether the student or young surgeon intends to further the cause of surgery as a clinician or as an investigator, a thorough knowledge of the principles included in this small book should help him acquire distinction in his field, extending the achievements of his predecessors." Even without the additional endorsements of such a well-known surgeon as Allen Whipple the candid reader cannot help agreeing with the sentiment expressed in that sentence. The principles of surgery are few, but they need to be inculcated at an early stage of the student's career and thoroughly explained so that he may apply them at every stage of his curriculum and practice. To try to learn surgery without first having a sound knowledge of these principles is to double the labour. Let the young student read, mark, learn and inwardly digest the contents of this book and he will lay a true foundation for his later work.

After giving that opinion we may perhaps be allowed to point out how the book might be further improved. Though the authors mention syphilis in the description of chronic infections they do not describe the tissue changes in gummatous inflammation, indeed there is nowhere an account of the infecting spirochaete or of the specific cures for the infection. They say that a boil is an abscess centred about a hair follicle, though they explain elsewhere that a slough of dead tissue comes away from it—that is, it is in reality a focus of infective gangrene. There is no mention of postural drainage for an infected knee-joint. In the section on actinomycosis we are told that "if the focus can be completely excised the result is good", we should not like to deny that, but we can assert that apart from cases of actinomycotic infection of the bowel excision should never be undertaken or considered until penicillin has been thoroughly tried. With these small points of criticism we leave the student to find out the merits of the book for himself.

ZACHARY COPE

### FOUNDATIONS OF NEUROLOGY

*Textbook of the Nervous System. A Foundation for Clinical Neurology* By H Chandler Elliott M.A. Ph.D. With an Introduction by Wilder Penfield M.D. (Pp 384, 158 illustrations, 62 subjects in colour and an atlas 48s) Philadelphia and London J B Lippincott Company

This is a remarkable little book which can be strongly recommended to those who wish to understand the foundations of neurology. The author expresses himself with great clarity, and his ability to simplify difficult facts must subdue the student's usual attitude of despair towards the subject. He explains the anatomical and physiological knowledge on which modern neurology is based in such a way as to rouse the student's interest to study some of the well-selected but not too numerous references given. Furthermore the author shows clearly where our knowledge of function ends and where it is merely groping to correlate a few facts. He gives the reader a balanced outlook which is rarely to be obtained from a textbook. There are many original and ingenious diagrams. For example in Fig 91 there is something about the human figure reclining between the red nucleus and the substantia nigra which will provide for most readers an enduring picture of the lamination of the medial lemniscus.

W RITCHIE RUSSELL

### HANDBOOK OF DERMATOLOGY

*Gardiner's Handbook of Skin Diseases* Revised by John Kinnear, OBE, TD, MD, MRCP, Ed, DL. Fifth edition (Pp 250, 20 coloured plates, 9 from Dufraycolour photographs 15s) Edinburgh E and S Livingstone 1948

This must be one of the smallest of the many textbooks of dermatology which have appeared in the last half century, containing as it does only 250 pages. It may well be asked whether this is an important point in its favour or not. Dermatology is a subject which is not well suited to dogmatic discussion. The skin is a very complex organ and the diseases to which it is subject are so multifarious and so interrelated that an adequate textbook of the subject must contain proper discussion of its problems at such a length that real brevity is necessarily excluded. Probably the original author of this book and his successor have been aware of this consideration but they have kept more in mind the needs of students, who are, as it were, pitchforked into the subject at a certain point of their clinical curriculum and become liable within a few months to satisfy examiners that they have some elementary knowledge of it. Readers in this category when faced with one of the exhaustive manuals of dermatology produced in almost ceaseless profusion by the dermatological specialists of Europe and America are apt merely to be impressed with the difficulty of the subject, to fail to discover any sound principles therein on which to base their own practice, and to be confused by the multiplicity of details. This little book is admirably adapted to the needs of such as these. It is clear, accurate and brief, and for its size it is very well and amply illustrated.

The introductory chapter is particularly good, and it is gratifying to see that the author draws attention to the complexity of functions undertaken by the skin, a complexity that no doubt accounts for the great variety of the pathological changes to which it is subject. He has brought this edition thoroughly up

to date and discusses well the many advances in therapeutics which we owe to the skill of our chemists and pharmacologists. Perhaps the author might have written rather more extensively on dermatitis and/or eczema, for this is the commonest and most important of all skin diseases now that social education has reformed the habits of the many, and it therefore requires consideration at length even in an elementary textbook. But by and large this is an excellent introduction to dermatology for students, and if they take the trouble to digest its contents during their three months' attendance at the out-patient clinic they will become better and wiser practitioners.

H HALDIN-DAVIS

## MEDICINE IN GENERAL PRACTICE

*Internal Medicine in General Practice* By R. P. McCombs M.D., F.A.C.P. Second edition (Pp 741, 122 illustrations 42s.) Philadelphia and London W. B. Saunders Company 1947

If it is held that the general practitioner's effective future depends on his capacity to become an efficient general physician then this book surely deserves a welcome. To earn a wide regard, however, such a book must prove that it meets the needs of the family doctor better than do the standard textbooks of medicine here and in the USA. Dr McCombs can claim this, for his book is a little cheaper and less than half the size (741 pages) of its established rivals. Since it is written by one man it has a uniformity of conception and performance which these other books notably lack, moreover its author seldom loses sight of the whole patient in the enthusiastic concentration upon one part of him. He knows, too, the needs of the family doctor and the errors that may betray him, and the account of each system is preceded by a discussion of symptomatology and diagnostic methods which is altogether admirable. These are great merits, but the book cannot be unreservedly recommended to the British doctor.

The attention given to certain diseases is inadequate, for example diseases of the nervous system are described in no more than one eighteenth of the total space—cerebral tumour being dismissed in half a page. While this book has the excellent American practice, now followed in Britain, of giving a relevant bibliography at the end of each chapter, the references are almost exclusively American. It is apparent that a familiarity with the English literature would have led the author to change the presentation of certain sections of the book—as, for example the accounts of renal disease, heart failure, liver disease, and gastritis. (It is an odd result of the economics of American medicine that in the account of the investigation of gastrointestinal disorders the author states that "the cost of x-ray study precludes its use as a nearly routine measure".)

Finally and most important, a reduction in size of a textbook of medicine must be obtained by the exclusion of material previously regarded as relevant. Dr McCombs has chosen to omit consideration of the basic sciences, nearly all the pathology and most of the physiology and anatomy which to day find their way into the orthodox textbook. The fundamental knowledge, one would surmise that the family doctor is most in danger of forgetting is thereby excluded. The book is well produced and nicely written, it is accurate and its information is up-to-the-minute (there are accounts of streptomycin, nitrogen mustard, folic acid, radioactive iodine and cytochrome C), but it must be judged to fail not in its execution but in the initial misconception of its purpose.

D. V. HUBBLE

It has been said that a medical student must learn the equivalent of a foreign language in order to master sufficient of the nomenclature needed to understand medical works, and all medical men no doubt pay some attention if only fleeting, to the structure of our terminology. Perhaps we are not critical enough else why should we accept such peculiarities as "antibiotic" and "deratization" so easily? Mr Peter D. Ridge-Beedle, in *Why Not English?* (Stratford Press, 10s. 6d.), criticizes another aspect of the English language—its spelling—and propounds a reformed system that necessitates 42 letters in all. The author's system is not itself consistently phonetic for he uses the same sign 'r' for the "er" sound of "father" and the 'r' sound in "rough". The obstacle of varying pronunciation appears in his spelling of the word 'language,' the last syllable of which he treats as if it rhymed with 'age,' whereas many would rhyme it with 'midge'.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Vitamine und Vitamintherapie* By E. Abderhalden and G. Mounquand (Pp 408 28 Swiss francs) Bern: Huber 1948  
A general account of clinical and experimental work on the vitamins

*Endocrinology of Neoplastic Diseases* Edited by G. H. Twombly, M.D., and G. T. Pack, M.D. (Pp 392 60s) London: Geoffrey Cumberlege 1947

A collection of papers by various American authorities

*Pathological Processes in Malaria and Blackwater Fever* By B. Maegraith, M.A., M.B., D.Phil., B.Sc. (Pp 430 35s) Oxford: Blackwell 1948

An account of the clinical and pathological aspects of malaria and blackwater fever, with references

*Myotonia* By E. Thomasen (Pp 251 20s) London: H. K. Lewis 1948

A monograph on the clinical aspects, treatment, and inheritance of the myotonias

*Eat and be Healthy* By L. Nicholls, M.D. (Pp 56 4s. 6d) London: Associated Newspapers of Ceylon 1948

Instruction on sound diet for the layman in Ceylon

*Hodgkin's Disease and Allied Disorders* By H. Jackson, Jr., A.B., M.D., and F. Parker, Jr., A.B., M.D. (Pp 177 45s) London: Geoffrey Cumberlege 1947

An account of the pathology, symptomatology, and treatment

*Aids to Organic Chemistry* By S. F. Smith, M.B., B.S. 3rd ed. (Pp 127 4s. 6d) London: Baillière, Tindall and Cox 1948

Intended for medical students

*Die Morphogenese der Hypertrophie und des Karzinoms der Prostata und ihre Bedeutung für die Klinik* By R. Howald (Pp 40 4 Swiss francs) Basle: Schwabe 1948

A monograph on prostatic hypertrophy and carcinoma, with photomicrographs

*Veterinary Protozoology* By U. F. Richardson, B.Sc., M.R.C.V.S. (Pp 240 18s) London: Oliver 1948

An account of the protozoa that attack animals, particularly in the Tropics

*Plant Vnuses* By K. M. Smith, F.R.S. (Pp 78 6s) London: Methuen 1948

An introduction for the botany student or general reader

*La Mortalité de L'Enfant de Première Année* By C. Candiotto and C. Moine (Pp 64 No price) Paris: Baillière 1948

A monograph on infantile mortality in France

*A Primer in Clinical Science* By R. D. Wright (Pp 43 3s. 6d) London: Melbourne and Oxford University Presses 1948

An introduction to clinical work for the student

*Jaundice: Its Pathogenesis and Differential Diagnosis* By E. R. Movitt, M.D. (Pp 261 42s) London: Geoffrey Cumberlege 1947

A practical manual for the clinician with bibliographies

*The Use of Isotopes in Biology and Medicine* By H. T. Clarke and others (Pp 445 \$5.00) Madison: Wisconsin Press 1948

A symposium on the use of isotopes in research

*Recherches Personnelles pour Servir à L'Étude de la Gonococcie* By A. Guepin (Pp 218 No price) Paris: Presses Universitaires 1933

An account of the author's experience in treating gonorrhoea

*Research Reports: Feeding Problems in Man as Related to Environment* By R. E. Johnson, M.D., D.Phil., and R. M. Kark, M.R.C.P. (Pp 94 No price) Chicago: U.S. Army Medical Nutrition Laboratory 1947

An analysis of U.S. and Canadian army ration trials and surveys during the recent war

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 7 1948

## WORLD HEALTH ORGANIZATION

The World Health Assembly of the World Health Organization concluded its first meeting on July 24 after being in session for a month, during which the various committees (each a committee of the whole) were unremitting in their attention to the problems before them. Sixty-eight nations were represented by delegates and observers on this historic occasion, and the first meeting of the World Health Assembly provided a notable illustration of the well-worn saying that medicine knows no frontiers. The remarkable measure of agreement reached and the spirit of co-operation displayed were in no small part due to the skill and tact with which the President of the Assembly, Dr Andrija Stampar, of Yugoslavia, conducted its deliberations, and, also in no small part, to the efficiency of the secretariat under Dr G Brock Chisholm, newly appointed Director-General of WHO, who for the past two years has been acting as Executive Secretary to the Interim Commission. The work of the Assembly completed, the first meeting of the Executive Board was held, with Dr A T Shousha Pasha as Chairman and Dr K Evang and Dr W W Jung as Vice-chairmen. The immediate problem before WHO is the establishment of a permanent central staff under the Director-General and the setting on foot of projects considered to be urgent. It is expected that the Executive Board will meet in the autumn, when its eighteen members (representing eighteen States) will have had the opportunity to consider at greater leisure the numerous matters discussed in June and July. The first legislative act by WHO has already been performed by the issue of regulations laying down detailed methods of procedure to be used by the various member countries in the compilation of data on diseases and causes of death.

It will naturally take a little time before the central staff at Geneva finds its working feet, and it is therefore in some ways a pity that five of the regional organizations are to be set up before the central administration is firmly established. The six regions into which for the purposes of WHO the world is to be divided are European, Eastern Mediterranean, South-East Asian, Western Pacific, African, and North and South American. The last named has of course been admirably served for years by the Pan-American Sanitary Bureau, and negotiations are on foot for its integration in WHO. The desire to establish quickly offices in the other five regions is understandable, and with the good will displayed by the member States in the World Health Assembly difficulties that may arise should be easily solved. But the project which WHO has in hand is so tremendous in its implications that it would be a mistake if the desire to get something done speedily for reasons of prestige or justification were to encourage initial imperfection of

organization. The plans for the work of WHO must of necessity be worked out from year to year and framed in accordance with its annual budget. But it is not fanciful to suggest that the ideal that it has set itself would need a long-term policy conceived in terms of decades rather than calendar or financial years. It would seem, therefore, of the first importance that the foundations of its central and regional organizations should be laid with the utmost care if the structure to be raised upon them is to be adequate to the high purpose WHO has set itself of "the attainment by all peoples of the highest possible level of health."

To begin the first year of work of WHO the Interim Commission had proposed a budget of \$6,500,000 for 1949, and a decision to cut this to \$5,000,000 (about £1,250,000) came as a disappointment to many. It certainly seems a small enough budget with which to start health activities on a world-wide scale. Nevertheless, the expenditure of the United Nations and its specialized agencies amounts in all to a vast annual sum, about half of it being contributed by the USA. The sceptic might reflect that if the money spent by the United Nations was put at the disposal of WHO, in exchange for WHO's budget of \$5,000,000, the world would be a healthier and happier place to live in. But discarding this proposition as Utopian, we may believe WHO will find it will achieve concrete results by having to concentrate on carefully selected programmes of manageable dimensions. The six principal health problems it has decided to tackle in 1949 are malaria, tuberculosis, venereal disease, maternal and child health, nutrition, and environmental hygiene. These are matters which call for five- or ten-year plans, and even then so much depends upon the social and economic conditions, sanitation, personal and communal habits of different peoples that the success of an attack upon, for example, tuberculosis will reside as much in the solution of these as in preventive and curative measures. Granted peace, improved sanitation in backward areas, the alleviation of social and economic distress, there yet remains the provision of enough well-trained doctors and nurses and all the other skilled equipment of modern medicine. Beyond this there is the inculcation among peoples of the principles of health and hygiene. Many of these things are in the control of forces outside the world of medicine, but medicine has one potent instrument which it can put at the disposal of regions less favourably placed than, say, the USA—and that is expert knowledge. WHO should be a power-house of information on all those matters which come within its purview, and the insistence of many delegates at Geneva on the importance of the editorial and publications services of WHO showed their live awareness of this fact.

It may be pertinent here to trace the development of the idea of the international control of disease, which has now progressed to the idea of the international promotion of health. Quarantine as a protection against plague was introduced into the Mediterranean in the fourteenth century, the inspiration for this coming from the observations on leprosy in Leviticus. And similar action was taken in North America in 1647 against the fever (yellow fever) in Barbados. The spread of Asiatic cholera across Europe in the first half of the last century reminded Europe once

more that infectious agents are indeed international, and a formal international sanitary convention was drawn up at a meeting of the International Sanitary Conference in Venice in 1892<sup>1</sup>. The first health agency to operate for several Governments was, however, the Pan-American Sanitary Bureau, established at a conference at Washington in 1902. In 1909 the Office International d'Hygiène Publique (OIHP) was set up in Paris, and operated until 1946, when the decision was taken to amalgamate it with WHO. With the appearance of the League of Nations after the war of 1914-18 it was proposed to place international health bureaux under the authority of the League, but the OIHP continued its separate existence in a compromise arrangement with the Health Organization of the League—an organization which represented the one solid contribution the League made to human welfare. The war of 1939-45 naturally interfered with the work of OIHP and the League Health Organization, and the gap was temporarily filled by Unrra, whose activities ended in December, 1946, in Europe, and in March, 1947, in the Far East, some of its functions being transferred to the Interim Commission of WHO. The project of a new and comprehensive health organization was discussed at the United Nations conference in San Francisco in 1945, and in February, 1946, the Economic and Social Council of the United Nations set up a technical preparatory committee, which shortly after prepared draft constitutions for a world health organization. The next step was the holding of the International Health Conference in New York in June, 1946, when the constitution of WHO was signed by representatives of 61 States. The constitution was to come into force when 26 members of the United Nations had ratified their signatures, and the Interim Commission of 18 States undertook the preparatory work of establishment until ratification, it also continued the functions of former international health organizations and the consideration of urgent health problems. It was expected that the Interim Commission would have a life of only a few months, but this, in fact, was prolonged for about two years, ending with the official birth of WHO in April of this year.

There is not space here to enumerate the various activities of WHO IC during the past two years. We may note the completion of the Sixth Decennial Revision of the International Lists of Diseases and Causes of Death, the appointment of an expert committee on malaria, the extension of work on biological standardization, field services in epidemiology, the provision of travelling fellowships, work on an international pharmacopoeia, and in particular the emergency committee established during the cholera epidemic in Egypt in the autumn of 1947.

The conception of WHO is one that should appeal to the imagination, and indeed it will call for imagination on the part of those directing its activities if its work is not to be hampered by the natural defence mechanisms of bureaucracy. In full recognition of the great progress already made we may suggest that one of the problems of WHO will be to keep its organization flexible and of such a size that the Director-General will be able to

remain in close touch with his staff. In a recent broadcast Sir Lawrence Bragg observed that when an institution grew beyond a certain size its director—he was of course referring especially to research—lost that close touch with his subordinates which made for efficient and productive team work. Establishments have a natural tendency to grow, but it is to be hoped that the number of permanent officials in WHO will be small enough for the Director-General through personal contact with each one to take that close interest in their work which is essential if an institution is to be something a bit more than an efficient organization.

## MEDICAL AND SCIENTIFIC INFORMATION

The burden of the printed word to-day lies heavily on the world of science, an inevitable outcome of the great volume of research work carried out in the laboratories of pure and applied science in the universities, research institutes, and industrial organizations of so many countries. Our civilization is no longer one based on the humane studies, pervaded as it was with a sense of leisure and free from obsession with the time-table. We live in a technological age when the speed of discovery and the application of what is discovered bring with them a sense of impermanence and insecurity. The unceasing accumulation of facts daunts even the most comprehensive mind, and man's capacity for analysis far outstrips his ability to provide a synthesis. The man of science who contributes to knowledge finds himself working in ever-narrowing fields of inquiry, so intense has specialization become. The spate of publications makes it increasingly difficult for him to know what workers in adjacent fields are doing. "As a result," to quote from a document issued by the Royal Society for its Scientific Information Conference in June, "the task of keeping up with scientific literature is becoming an impossible one, and is in turn leading to inefficiency and to a certain amount of frustration in scientific research and in the application of science." The Royal Society has once more put the world of learning in its debt by holding such a conference, which was attended by delegates from the Dominions and other countries.

Unfortunately its meeting coincided with the Annual Meeting of the B M A at Cambridge, but the B M A was represented by the Editor of its two abstracting journals, Dr G M Findlay, and by Professor Samson Wright. The Conference tackled through four sections the following problems: (1) Publishing and distributing original scientific papers. (2) Issuing and using abstracts to convey current awareness of availability and relevance of such papers. (3) Consolidating abstracts or other forms of reference into continuously cumulative indexes and using these and other library services for the retrospective searching of the literature. (4) Producing and utilizing periodical reviews of progress in designated fields of science. A number of valuable notes and memoranda were made available. If scientific knowledge is becoming unmanageable it is interesting to note that the science of documentation is providing methods to keep pace with it. Most are familiar with the use of the photostat and microfilm, but new to many will be the Dutch invention whereby "a foolscap page can

<sup>1</sup> For this and other information see *Official Records of the World Health Organization* No. 9.

be reproduced within the dot of a letter 'i,' or the whole of the *Encyclopaedia Britannica* on three quarto pages" This method enables very minute microphotographic images, legible through a microscope, to be printed on a paper base. Another Dutch invention uses diazo instead of silver chemicals for reproduction by reflex photography. New mechanical methods may revolutionize the method of presenting and distributing information and may yet be linked up with Professor J. D. Bernal's proposals for distributing scientific papers, the value of which was somewhat obscured by the controversy surrounding it at the outcome of the Conference.

Whatever direction future developments may take, abstracts of current scientific literature will become of increasing importance. The medical man who does research work is under the same pressure of specialization as other workers in science. There is hardly any field of medicine in which the observations and methods of the pure sciences do not find some point of application. The clinician who specializes tends to do so at the expense of his knowledge of medicine as a whole. To provide a synoptic view of medicine is the aim of *Abstracts of World Medicine*, and *Abstracts of World Surgery, Obstetrics and Gynaecology*. In his editorial notes for the Royal Society Conference, Sir David Chadwick observed that "the indefinite multiplication of largely unrelated abstracting agencies and of abstracts journals is not, however, a good solution"—an observation made under the heading of "Promptness in Issue of Abstracts". To grapple with this question in Medicine Unesco has during the past eighteen months<sup>1</sup> set up an Interim Co-ordinating Committee on Medical and Biological Abstracting in Paris to examine the situation and to look into possible ways of collaboration among existing medical abstracting agencies. The outcome of its penultimate meeting was discussed in a leading article in the *Journal* of Oct 11, 1947. The preliminary survey thus made was thought by the General Assembly of Unesco to justify the setting up of a co-ordinating committee in medical abstracts under the aegis of Unesco, whose function is that of convener and secretariat. At a meeting in Paris in April of this year under the chairmanship of the Editor of the *British Medical Journal* the matter was carried a stage further in a two-day conference in which representatives of the following organizations took part: *Abstracts of World Medicine*, *British Abstracts*, *Excerpta Medica*, International Federation for Documentation, Medical Library Association, U.S.A., and the International Federation of Library Associations. In addition to representatives of the above as members of the Committee, the United Nations, the World Health Organization, *Chemical Abstracts* and Ingeniors Vetenskaps Akadmién (Stockholm) sent observers who made valuable contributions to the conference. The meeting was organized by the Natural Sciences Division of Unesco under its director, Dr. Joseph Needham, and the Medical Counsellor of the Division, Dr. I. M. Zhukova. The meeting in April was of value in that those with expert knowledge of various aspects of documentation were able to pool their information and exchange ideas on what on the surface would appear to be a somewhat dull subject but is far from being

so. Towards the end of the meeting it became clear that there was enough useful and indeed urgent work to be done on the subject of medical abstracting to justify dropping the word "Interim" from the title of the Committee if other organizations see fit to become members of it. It was resolved, for example, that WHO and FAO should join Unesco in sponsoring the activities of this Committee, and this WHO has now agreed to do. Invitations have been sent to other abstracting agencies to join in the work of co-ordination, and it is hoped that a full meeting will be held in the early part of next year.

In a world which modern transport has reduced to a manageable unit of travel and communication the specialized agencies of the United Nations—Unesco, WHO, and FAO—have a greater chance of promoting international understanding than the parent world organization. If there had been any suspicion that Unesco was merely pursuing an academic exercise in seeking to co-ordinate the activities of medical abstracting this should have been removed by the stress laid upon this kind of work by the Royal Society conference in June. To translate discussion into action will be the problem of the Co-ordinating Committee on Medical and Biological Abstracting in its future conferences.

## NITROGEN MUSTARD

The therapeutic development of the nitrogen mustards or alkylamines is an example of the beating of swords into ploughshares, for it was following the observation of the effects of mustard gas on the haemopoietic tissues that the nitrogen compounds came to be employed in the treatment of Hodgkin's disease, leukaemia, and allied disorders. We publish elsewhere in this issue a paper by Dr. D. C. Sinclair on mustard-gas poisoning. Much of the experimental work with this substance could not be published at the time it was undertaken, and it is now evident that "security" robbed Dr. J. F. Wilkinson<sup>1</sup> and his colleagues in Manchester of priority in describing the therapeutic use of the nitrogen mustards, since their results were available to the American workers<sup>2,3,4</sup> in the same field who are generally given the credit for introducing these new drugs.

The two compounds used have been methyl-bis( $\beta$ -chloroethyl)amine hydrochloride and tris( $\beta$ -chloroethyl)amine hydrochloride. Both these substances are readily soluble in water, in which they rapidly undergo chemical rearrangement, forming first cyclic ethylene-imonium derivatives with powerful effects on mitosis and intracellular enzyme systems, and later other relatively inactive compounds. Most workers have used the "bis" compound, but there is no significant difference between the effects of the two. The initial dose has usually been 0.1 mg per kg of body weight, repeated on consecutive or alternate days until three to six doses have been given. It is administered intravenously, with precautions to avoid leakage into the subcutaneous tissues, for the nitrogen mustards retain the vesicant properties of mustard gas. Nausea and vomiting three or four hours after injection almost always

<sup>8</sup> *Blood* 1947, 2, 564.

occur, anorexia and headache are common during the three or four days of the drug's administration. The effect on haemopoiesis is apparent within two to five days and is commonly greatest by the 18th day after injection. The total leucocyte count falls in every instance, the first change is a lymphopenia, and this is rapidly followed by a neutropenia. With the doses in common use it is unusual for the leucopenia to be less than 2,000 per c mm, and a true agranulocytic syndrome occurs in less than 1%. Thrombocytopenia is less frequent, and the count seldom falls below 60,000 per c mm, but transient purpura has been noted. The effect on the erythrocyte count is variable and usually insignificant.

The therapeutic activity of the alkylamines has now been studied in a number of the proliferative and neoplastic diseases of haemopoietic tissue, and it is justifiable to attempt some assessment of their value. There is a remarkable unanimity in the numerous reports available.<sup>5,6,7</sup> Hodgkin's disease responds satisfactorily, and remissions lasting several months have followed a single course of injections, but they are usually shorter than after irradiation. Most workers have been impressed with the improvement shown by some patients in the stage of terminal cachexia and with the rapid relief of pain due to skeletal infiltrations. Nevertheless the alkylamines will not cure Hodgkin's disease, nor do they appear to be in general as effective as radiotherapy. In the related disorders the results are less satisfactory, but chronic myeloid leukaemia can often be controlled, and in the other reticulososes and in reticulosarcoma temporary improvement was sometimes seen. In myelomatosis and most epithelial neoplasms the results were bad, though occasionally patients with bronchial carcinoma have improved remarkably. Remissions were obtained in a proportion of patients with polycythaemia vera. An unsatisfactory result in a case of this disease is described by Dr A. W. Woodruff on page 299 in this issue. The initial fall in red blood cells was considerable, but thereafter the tendency to rise again was not controlled by further treatment. Mycosis fungoides varies in its response, most workers report indifferent results, but Henstell, Tober, and Newman<sup>8</sup> recorded immediate and striking remissions in six patients. They found that nitrogen mustard was most successful when reticulum cells dominated the cutaneous infiltrations, and they concluded that the drug had a selective action on this cell.

The importance of the nitrogen mustards lies not in their immediate therapeutic application but in the discovery of a group of chemical substances which have a lethal action confined to one particular type of cell. It is possible that more powerful and more specific drugs will become available, since numerous compounds related to the nitrogen mustards could be synthesized and given clinical trial.

### LIVE AND DEAD YEAST

The value of dried autolysed yeast as a source of some members of the vitamin-B complex is undoubted, and this material has been widely used by patients with symptoms of chronic vitamin deficiency. However, the usefulness of live yeast has not been so certain, and a group of workers<sup>1,2</sup> at Wisconsin University have recently obtained very different results with live and dead yeasts. In a series of experiments they found that the addition of up to 150 g daily of fresh yeast to the diet of normal individuals did not have the expected effect of increasing the urinary excretion of riboflavin, and that in the case of vitamin B<sub>1</sub>,

the urinary excretion actually decreased. Analysis of the faeces showed that the vitamins had not been absorbed. The same results were obtained with three types of dried yeast which still retained life. Only dead yeast was found to increase the urinary excretion of riboflavin and aneurin. The conclusions drawn from these results are first that live yeast, though containing a large concentration of vitamin B<sub>1</sub> and riboflavin, is not in practice a good source of these vitamins, since they cannot be absorbed from the living cells, and therefore pass into the faeces; secondly, the living yeast appears actively to compete in the gut for such other vitamin B<sub>1</sub> as is available, and so actually reduces the amount that might be absorbed.

These results, if they remain undisputed, serve to point out the complexity of the factors which may affect the nutritional status of a patient. It is now realized, for example, that the requirement of a particular vitamin may vary with the quantity and quality of protein in the diet, indeed it seems likely that nicotinic acid is not needed at all if the diet contains sufficient tryptophan. Again, the microbiological synthesis of vitamins in the intestinal tract may be a significant source for man as well as for the ruminants. In the light of all these findings the too rigid use of tables of vitamin requirements and food contents seems unjustified.

### TREATMENT OF TYPHOID CARRIERS

The typhoid bacillus was formerly classed as a penicillin-resistant organism, but it is in fact the least resistant of the intestinal pathogens and must be classed among the bacteria which, in theory at least, can be successfully attacked with high concentrations of the drug. R. W. Evans<sup>1</sup> examined 66 strains and found that the concentration required to inhibit growth completely varied from over 25 (in only 1 strain) to 10 units per ml, which inhibited the majority. Lower concentrations retarded the growth of many strains, and sensitivity was unrelated to phage type. J. W. Bigger was the first to show that sulphathiazole acts synergically with penicillin on *Salm typhi*, this action was studied and confirmed by G. T. Stewart<sup>2</sup> and by J. C. Thomas and W. Hayes,<sup>3</sup> whose elaborate experiments took into account every possible variable and fully confirmed previous belief that concentrations of the two drugs which are attainable therapeutically in certain situations should have a marked effect. Bigger's observations led directly to a trial by C. J. McSweeney<sup>4</sup> of the action of the two drugs in combination on typhoid fever; he reported very favourable results in six cases. The treatment was vigorous, penicillin being given at only two-hour intervals in doses of 200,000 units and sulphathiazole at the rate of 1g three hourly for periods of four days. Trials of this form of treatment in several Army Commands, reported by C. G. Parsons,<sup>5</sup> did not confirm the favourable impression formed in Ireland, but it is to be noted that McSweeney's treatment schedule was not exactly followed, in particular the interval between penicillin injections was longer in almost all cases, and, since the maintenance of a high concentration is obviously desirable, this may have been an important factor.

The possibility that typhoid carriers might be cured by this treatment has not been overlooked, but hitherto no adequate series of such cases has been studied. On page 295 of this issue R. M. Fry and his colleagues now report such a series. They studied the *in vitro* sensitivity of the strains of *Salm typhi* concerned to the two drugs separately and in combination, and, though the evidence of synergic effect

<sup>2</sup> Kingsley H. N., and Parsons H. T. *Ibid* 1947 34 321

is perhaps less striking than that afforded by the experiments of Thomas and Hayes, it is sufficient to encourage hopes of effective *in vivo* action from large doses. They also confirmed that penicillin given in large doses intramuscularly is excreted in considerable concentration in the bile. Nevertheless the treatment of seventeen persistent carriers with penicillin and sulphathiazole gave singularly disappointing results. Three systems of treatment were tried employing progressively huger doses of penicillin, culminating in 40 million units of penicillin together with 12 g of sulphathiazole daily. Courses of both continuous and intermittent treatment were given. The net result was the apparent cure of only three of the seventeen patients. This is certainly not encouraging, and further search must be made for some chemotherapeutic procedure which will deal more successfully with these patients. It would be a mistake to interpret the results as evidence against the efficacy of these drugs in typhoid fever itself. To eliminate an organism from the body altogether is a far more difficult task than to suppress its activity sufficiently to alleviate an acute infection. There are other infections, notably streptococcal, of which the acute form is highly susceptible to chemotherapy while the carrier state is often resistant.

### THE REFLECTING MICROSCOPE

The action of the Nuffield Trustees in making a grant to the University of Bristol for the construction and development of the reflecting microscope designed by Dr C R Burch, of the Department of Physics of that University, is an indication of the potential value in research of this appliance. At the recent exhibition in London arranged by the Physical Society Dr Burch and his co-workers described some of the uses to which the reflecting microscope may be put. It is not to be supposed that the normal refracting microscope is in danger of being supplanted. Difficult technical procedures, including the precision testing and polishing of aspherical surfaces, will limit the production of the reflecting type of instrument, and it may be expected that its uses will be confined to those in which it offers specific advantages. One of these is a substantial increase in working distance. The existing reflecting instruments have a numerical aperture of 0.98 with oil immersion and 0.65 without. Yet the working distance can be 14 to 20 mm. This is of obvious convenience in micromanipulation, which is a sufficiently difficult technique without the further handicap of the more restricted working distance imposed by a refracting microscope of high magnification. In metallurgical research the increased working distance permits the examination of the surface changes which take place in alloys at temperatures up to red heat and somewhat beyond.

The second main advantage arises from the fact that the optical properties of a mirror system are independent of wavelength. Dr R Barer, of the Department of Anatomy and Physiology at Oxford, has been examining this aspect of the reflecting microscope, and though his work is still at an early stage sufficient has been done to indicate the technical possibilities of the method. One series of measurements has been on the absorption profile of a red cell over a range of wavelengths extending well into the ultra-violet. For this purpose there is a substantial advantage in a system which can be operated over a continuous range of wavelengths. The reflecting microscope can be used with shorter wavelengths than a refracting ultra-violet microscope. To what extent this may be an advantage for the normal purposes of microscopy must be a matter of opinion. There are those who consider that the probability that changes will be produced in the

material under examination—or, as such critics would say, under bombardment—outweighs the advantage of greater resolution from shorter wavelengths. The instrument should not, in any case, be regarded as rendering obsolete the refracting type of ultra-violet microscope, of which a new British representative was shown at the Physical Society's exhibition. The two should rather be regarded as complementary. In biological research the reflecting microscope is likely to be particularly useful for measuring selective absorption, as, for example, in the study of carcinogenetic substances.

The immediate programme is for the production of ten reflecting microscopes of the existing type, and as a long-term project for the development of an instrument with the highest possible aperture. This will involve the use of two aspherical surfaces instead of one in the objective. If reflection is also employed in the condensing system four aspherical surfaces will be required. This is no easy programme, for with more than one aspherical surface axial alignment must present greater difficulty. None the less it is hoped that a numerical aperture in the neighbourhood of 1.4 may be attainable.

### VASCULAR CHANGES IN SILICOSIS

The effect of silicosis on the pulmonary circulation is a subject on which there have been differences of opinion, and a study made by Geever<sup>1</sup> on the pulmonary vascular lesions and related pathological changes in 43 cases of silicosis is, therefore, of interest. The cases were unselected and consecutive, but were uncomplicated by gross pulmonary tuberculosis, they were compared with a similar control group of men over the age of 50. The author prepared sections of 40 pulmonary vessels of all sizes from each case, and he classified the silicosis into discrete nodular and massive conglomerate nodular forms. In the discrete nodular form the vascular lesions were not prominent and were found mostly in the arterioles, venules, and capillaries, whereas in the massive conglomerate form the vascular lesions were severe and were found in vessels of all sizes. These findings agree with those of the French school led by Policard,<sup>2</sup> which up to the present has done most work on this aspect of silicotic pathology. Fibroblastic proliferation is the first reaction in all layers of the arterial wall, followed by proliferation of capillary channels and degeneration of muscle and elastic tissue. The final result is occlusion and disruption of the vascular wall by infiltrating granulation tissue, which invades all the layers. Sometimes even thrombosis of large arteries occurs.

In 26 out of the 43 cases right ventricular hypertrophy was found, and in 11 of the 23 patients with massive conglomerate disease failure of the right heart occurred. These findings confirm the physiological observations of Cournand<sup>3</sup> and his colleagues, who showed that pulmonary arterial hypertension existed in two out of the three silicotic patients whom they studied.

These vascular changes are also important, because they probably are partly responsible for cavity formation. Gough<sup>4</sup> has shown in his lung sections that areas of progressive massive fibrosis in South Wales coal-miners frequently have a central cavity. Gardner,<sup>5</sup> while discussing pneumoconiosis of all types, mentioned anaemic necrosis as a cause of the irregular slit-like cavities which are found in silicotic fibrous masses, and Vorwald<sup>6</sup> also considered that the cavitation which occurred in conglomerate nodular fibrosis was secondary to interference with the blood supply.

## Nova et Vetera

### THE FIRST ENGLISH MEDICAL JOURNAL

It has been stated<sup>1</sup> that the first English medical journal was the *Medicina Curiosa* only two numbers of which were published—in June and October, 1684. This claim has never been challenged, and if the term 'medical journal' is taken to mean a periodical devoted exclusively to medicine, then the *Medicina Curiosa* has no rival. It is not however, the first English journal dealing with medicine. Two and a half years earlier, on Jan 16, 1682, there was published the first number of what is undoubtedly the first English abstracting journal, and at least one-third of its space was given up to accounts of medical books and papers. This journal is now very rare and appears to have been overlooked by the medical historian (it is not mentioned even in Garrison's comprehensive list of seventeenth- and eighteenth-century medical and scientific periodicals), yet the quantity and importance of its medical contributions far exceed those of the *Medicina Curiosa*.

It appeared with the captivating title *Weekly Memorials for the Ingenious or An Account of Books lately set forth in several Languages With some other curious novelties relating to Arts and Sciences*. Each number consisted of eight small quarto pages, and its object was clearly stated in the preface to the first number:

"I cannot doubt but that this weekly paper will find a candid and cheerful acceptance amongst all ingenious persons, the design of it being to present them with a short view of the worthy Labours daily set forth by the Learned. The bare Titles of Books yearly printed in our Common Catalogues, are somewhat dry things, scarce able to raise in men that gust and appetite to Learning, which we may hope these brief Accounts will give them. I shall not confine my self in my Undertaking onely to Authors of our own Nation, but shall likewise give Accounts of most Books transmitted to us from all other parts, and shall transcribe here as most valuable, as well in reference to Accounts of Books, as to other curious Novelties therein contained, and of these I may in time communicate what I may receive from elsewhere."

The anonymous writer of this preface was thought to be a certain Mr Beaumont, who, after the appearance of nine consecutive numbers, quarrelled with his publishers, Henry Faithorne and John Kersey, and on March 20 began to produce a rival journal with an identical title which was published by R Chiswel W Crook, and S Crouch. Undeterred, the original publishers carried on with their project until the end

of the year and produced fifty consecutive numbers. Beaumont's rival weekly expired after the twenty-ninth number.

The editor of the modern abstract journal surveying the ever-growing mass of medical and scientific periodical literature, must envy the leisurely task of his seventeenth-century forerunner. There were few journals of any kind in Europe at that time. The *Journal des Scavans* first published in January, 1665 anticipating the *Philosophical Transactions* of our own Royal Society by three months, was the first scientific journal in any modern European language. Nicolas de Blegny's *Nouvelles Descouvertes* (1679) was the first medical journal in the vernacular.<sup>2</sup> The well-known *Acta Eruditorum* did not begin until 1682. Abstracts of papers appearing in these journals were printed in the *Weekly Memorials* but books

were still the chief source of up-to-date information, and substantial abstracts of important medical books form the chief item in many numbers. The greater part of Nos 4 and 7 is taken up by an abstract of the first volume of de Blegny's journal, in the Latin translation made by Theophile Bonet and published at Geneva in 1680 with the title *Zodiacus Medicogallicus*. No 6 contains an account of a work by John Collins (London, 1682) on salt and its use in food-preserving, and a description of "The Physick of the Americans of Virginia" from the *Journal des Scavans*. *The Observationes Physico-Medicae* of Johann Helliwig is summarized in No 9, and a fortnight later the place of honour is given to a report of the biochemical and pharmaceutical experiments described in J H Juncken's *Chymia experimentalis Curiosa* an account which is continued in No 15. The inaugural dissertation of G W Wedel on arthritis is noticed in April, and an account of the same author's book on setons, or "artificial issues"—then popular as a preventive against plague and fever—occupies a half of the number for May 22. One of the most interesting seventeenth-century accounts of the

Chinese system of medicine, especially of the pulse theory, was the *Specimen Medicinae Sinicae* by Andreas Cleyer, published at Frankfurt, in 1682, and a good summary of this work is given in No 21.

The publishers of the *Memorials* did not hesitate to include abstracts of their own publications, such as the celebrated John Ray's *Methodus Plantarum nova* (24) and the little classic on

<sup>1</sup> P Johnston Saint. The First English Medical Journal, *Med Press and Circ* 1939 201 117. Douglas Guthrie. *A History of Medicine*, 1945, p. 192. London: Nelson.

<sup>2</sup> *Bull Hist Med* 1934 2 285.

<sup>3</sup> This claim has been challenged by Eugène Guizard in his book *Deux Siècles de Presse au Service de la Pharmacie* (Paris 1913). He gives priority to the *Mémoires concernant les Arts et les Sciences* of J B Denis (1672), thus offering a curious parallel to the claims made in this article for the *Weekly Memorials*.

*Exercitatio Anatomico-Medica de Glandulis Intestinorum, earumque usui & Affectionibus, cui subiungitur Anatomie Ventriculi Gallinacei Studio Joh. Conradi Peyer Amstelodami, 1681 8vo*

**T**he Anatomical knowledge of the Stomach, and Guts, gives so great an insight into the Natures, and Operations of Aliments, Medicines, and several Diseases, that this Curious and Industrious Anatomist has been encouraged thereby to bestow much time, and pains in the search, and discovery of those Parts, and having taken notice that Dr Willis has given an exact Description of them, yet he assures the World, that they are more accurately done by Wepfer, so our Author thinking with himself, that he could add nothing alter two such great Men, makes choice of the Glandules only, for his subject, which he hath cultivated to that degree, as none ever did before him.

In the first place he gives the Reader the Situations, the different Figures, Magnitudes, Colours, Number, and Substance of these Glandules in the several Guts, together

No 30, with the first account in English of "Peyer's patches" (By courtesy of the Wellcome Historical Medical Museum)

brain surgery by the Plymouth surgeon James Yonge (29). The interest and importance of the matter in any abstract journal always depend upon the quality of original work available at a particular time, and in this respect the year 1682 seems to have been a fortunate one. In the latter half of the year the names of J. C. Peyer (Peyer's patches) and J. C. Brunner ('Brunner's glands') figure prominently in the *Memoriales Peyer's Parerga Anatomica et Medica Septem* (Amsterdam, 1681-2) is noticed at length in Nos. 30 and 32, and the account of Brunner's *Experimenta nova circa Pancreas* occupies more than two thirds of No. 37. Among other outstanding medical writers represented in the later numbers are J. J. van Meekeren, who was the first to record a bone-graft operation in 1668 and whose collected surgical observations, published at Amsterdam in 1682, are described in No. 43. High praise is given to the work of the celebrated Swiss physician Théophile Bonet, and the account of his *Mercurius Computatilis sive Index Medicopracticus* a forerunner of our modern 'systems of treatment,' closes with the suggestion that anyone who translated and published an English edition 'would do one of the best Pieces of Publick Service that ever has been perform'd in any Age, and next to the most Indefatigable and Learned Author himself, would deserve a Statue in all the Anatomical Theatres.' The influence of the *Weekly Memoriales* and the stimulus which it gave to English medical scholarship can be gauged from the fact that less than two years after this suggestion was made an English translation was published in a substantial folio volume by Thomas Flesher.

There is much else of medical interest to be found in these fifty numbers, but sufficient indication of the scope and value of the *Weekly Memoriales* has already been given to prove that it warrants consideration as a medical journal. If general agreement is forthcoming on this point then it must in future be regarded not only as the first English abstracting journal but as the earliest in our long line of medical periodicals.

## THE QUESTION OF LAY PSYCHO-ANALYSIS

BY

EDWARD GLOVER, MD

Formerly Chairman of the Training Committee British  
Psycho-analytical Society

The publication of a translation of Freud's essay on lay analysis could not have appeared at a more appropriate juncture,\* for the nationalization of teaching hospitals and clinics under the control of the Ministry of Health will sooner or later raise in an acute form the professional status of the lay worker. For the time being apparently the London Clinic of Psycho analysis has 'opted out' of the national service—a concession that could be the more readily granted in that the demand for trained workers in psycho analysis is notoriously in excess of the supply. The purveyors of a commodity in short supply can practically dictate terms to the consumer organization. Sooner or later, however, the position will change. Psycho analysis will be compelled to a closer affiliation with teaching organizations, and this in turn will involve a more official scrutiny of training methods and selection of candidates than at present exists. The recognition some years ago by a B.M.A. Committee that only students trained at psycho-analytical centres should be called "psycho-analysts" arose from an investigation of the alleged dangers of psycho analysis during which it was established that these sprang from the practice of "wild" analysis by untrained persons. But it was in no sense a binding pronouncement, and in practice meant next to nothing.

### Freud's Case for Lay Analysis

The arguments in favour of lay analysis "under conditions, presented by Freud in this essay, are roughly as follows. Starting from the premise that a quack is a person who undertakes

treatment without possessing the knowledge and capacity required for it, Freud pointed out that doctors themselves furnish the largest contingent of quacks in psycho-analysis. The training of medical students is almost exclusively in organic method, and the smattering of psychiatry they acquire is also non-psychological, certainly non-analytical, in tendency. Training in psycho analysis is lengthy and could not very well be included in an undergraduate syllabus, which, incidentally, to meet psycho-analytical requirements would have to include specialized courses in anthropology, sociology, language, literature, and the like—in a word, orientation in the nature of cultural development. On the other hand, apart from the desirability of having a "fine ear" for mental processes, the essential prerequisite of practice is a thorough "training analysis." The analysed layman who has learned the delicate technique of analysis and knows how to handle "transferences" and "resistances" is, in Freud's view, no longer a layman in the field of psycho-analysis.

He agreed however, that diagnosis and recommendation of treatment must remain a medical responsibility and that organic emergencies arising in the course of an analysis must be referred to a medical specialist, implying thereby that the lay analyst must work under medical supervision, but he pointed out that in the matter of organic crises even the medical analyst, being debarred from physical examination of a patient in treatment, must refer the case to a colleague for an opinion. Moreover, in the field of child upbringing and education many disorders of adaptation are found where the question of medical knowledge does not arise. It would in any case be impossible to stop the activities of such pedagogic analysts.

Finally Freud maintained that psycho-analysis deserves a better fate than to be "swallowed up by medicine and to find its last resting-place in textbooks on psychiatry—under the heading 'Therapy'." The theory of the unconscious mind 'may become indispensable to all the branches of knowledge having to do with the origins and history of human culture and its great institutions.' 'At all events, it would be unreasonable to sacrifice all other uses to this one [the therapy of neuroses] merely because it touches the field of professional medicine.'

### Future Status of Psycho analysis

Reviewing these arguments at a distance of over twenty years (the essay was originally published in 1926) it is interesting to note that Freud's uneasiness about the future status of psycho analysis was not altogether without foundation. Partly because psychiatrists have in the meanwhile come to recognize that a knowledge of clinical psychology is essential to their work, and partly because of the filip given to it by the second world war, psychiatry has gained a not altogether warranted prestige and authority in psychological matters. True, its tardy dalliance with the principles of psychology has since undergone a considerable regression, stimulated no doubt by experience of various electrical and drug therapies. But the authority of psychiatry in mental medicine has come to stay. This is in many ways unfortunate. Although a sound knowledge of psychiatry is essential to the understanding of early mental development, psychiatry has no prescriptive authority in general psycho analysis. Indeed, there is considerable evidence that an absorption in clinical psychiatry dulls the "fine ear" for therapeutic processes. On the other hand, lay workers, not being registered medical students, are debarred from acquiring even that bare minimum of psychiatric experience that is obligatory in the medical curriculum.

An equally interesting development has occurred in the field of child psychotherapy. As happened in the case of psycho analysis of adults, the practice of child analysis was soon bowdlerized, groups of so called "play-therapists" whose technique bears a very remote resemblance to that of child analysis have sprung up all over the place, indeed, play therapy now receives the blessing of most directors of psychiatric centres and child-guidance clinics. Admittedly this form of treatment is carried out "under supervision," nevertheless its official recognition indicates that psychiatrists have departed very considerably from the intransigent attitude they once adopted towards lay therapy.

Now, for all practical purposes these changes cancel each other out, leaving the issue of lay analysis very much where

\*Sigmund Freud *The Question of Lay Analysis* Translated by Nancy Procter Gregg London, Imago Publishing Co., 1947 (pp. 81, 9s.)

was Under these circumstances the best way to clarify the situation is to list the mental disorders treatment of which should be carried out exclusively by medically qualified psychoanalysts and those in which it could be carried out without medical risk by properly trained lay analysts We can then consider the advantages and disadvantages of a medical training and of a lay approach respectively

### Medical Analysts

In the first place it may be laid down that psycho analysis of the psychoses, of borderline or larval psychotic conditions, of psychotic character cases, of severe cases of psychopathy, of most conversion hysterias and some of the anxiety states, of the traumatic neuroses and psychosomatic disorders of alcoholism and drug addiction, should, either because of the medical risk involved or because of somatic complications, be carried out only by medical analysts The analysis of most anxiety hysterias, a few conversion hysterias, most obsessional neuroses, general character difficulties (excluding schizoid and paranoid types), of sexual inhibitions and perversions, of most antisocial disorders, and of childhood disorders (excluding psychosomatic and psychotic types) could safely be conducted by lay analysts, who in any case are free to carry out pedagogic analyses and analysis of normal persons for purposes of research or training

Diagnostic considerations and medical risks apart, the main advantage of medical training is not so much the acquiring of psychiatric knowledge, important as that is, as the development of a "sense of illness" Unfortunately this is discounted to some extent by the fact that most medical students are not psychologically minded This, however, is no argument against the medical training of persons who are psychologically inclined and wish to practise medical psycho-analysis That existing medical curricula are practically barren of psychological orientation is merely an indication of the urgent necessity to reform these curricula In any case it would be quite practicable for any medical student to start training in psycho-analysis at a recognized institute as soon as he had completed the first part of his M B

### The Lay Approach

So far the main arguments in favour of recognizing the treatment by lay analysts of mental illnesses that are not strictly "medical" are that lay analysts are not "spoiled" by organic training, that there is a shortage of medical analysts and that by restricting practice to medically qualified persons some lay analysts of unusual capacity might be excluded There is something to be said for the first argument The advantage is however offset by the lay candidates' lack of scientific training a fact which has led some Institutes to insist on an 'equivalent' such as a degree in general psychology or a Ph D Unfortunately a training in normal psychology blunts the "fine ear" just as much as concentration on organic factors, and a Ph D is evidence of intellectual discipline only More objectionable is the jealousy of their medical colleagues displayed by many lay analysts, who often take a pride in being more royalist than the King regarding every cold in the head as being psychologically determined Moreover, lay analysts tend to have a rather dim idea of professional codes

Undoubtedly there have been a few lay analysts of outstanding capacity but the percentage of these is not any higher than that found amongst medical analysts The truth is that neither medical nor lay candidates conform to the standard of cultural development that is desirable for those undertaking the analysis of mental phenomena Not, by the way, that it is any lower than the standard accepted for medical students Nor can this situation be improved by adopting new-fangled and often ridiculous methods of selection The most that teaching bodies can aim at is technical competence and they are lucky if they get it As for the shortage of medical analysts this is a short-term argument of diminishing validity It dates from the pioneer days when the medical profession was, almost to a man violently antagonistic to the theories of Freud, which incidentally they had rarely read and when some distinguished members of lay professions displayed their scientific temper and

imagination by devoting themselves to the study of psychoanalysis Being already in the middle years of life, it was not to be expected that they should spend another five or six years acquiring organic disciplines which under the then existing system of selection of cases they would not have occasion to use But times have changed and there is not now the same reason to exempt those who would adopt unrestricted psycho-analytic practice from taking a medical qualification

### Need for a Faculty of Medical Psychology

But when all is said the facts remain that non medical disciplines are just as essential to the study of psycho-analysis as training in organic methods and that many groups of cases can be expertly analysed with little more than an educated layman's knowledge of organic medicine It is clear, therefore, that the problem of lay analysis can be solved only provided universities and colleges create an alternative medical course Above all what is needed is the development of a Faculty of Medical Psychology By this I mean not just the appointment of Professors of Psychiatry or Directors of Psychiatric Centres qualified to prepare students for third-rate 'diplomas' in psychological medicine, but a faculty having power to confer special degrees in medical psychology It is not beyond the wit of university authorities to devise a course in psychological medicine in which training in organic disciplines would be drastically shorn of superfluous detail, which would give the student immensely more training in clinical psychology than is at present the case, and which would include chairs in anthropology, social and sexual disorders, the history of cultural development and all those ancillary studies which are essential to psychological training No doubt the further training of those who wished to specialize in psycho-analysis would of necessity remain in the hands of psycho-analytical institutes and clinics affiliated to the faculty But we might as well face the fact that the field of psychological medicine is as wide as if not wider than that of organic medicine and calls for elaborate and specialized training

This new creation would, however, leave two problems unsolved—namely, how to control methods of selection of psycho-analytical candidates, and how to ensure that they are soundly instructed in classical psycho-analysis Existing methods of selection should certainly be scrapped they are conspicuously unsuccessful The new degree in medical psychology would surely suffice for this purpose As for ways and means of ensuring that psycho analysis is soundly taught, that is a more ticklish problem Even in this country at the present time it has not proved possible to exclude from psycho-analytic teaching ideas and methods which would not be accepted by training institutes in other countries Possibly a system of exchange scholarships whereby a number of candidates could be trained at centres abroad would help to correct these parochial deviations from classical analysis But perhaps it would be enough if medical faculties ordered their own training on sound psychological lines, psycho-analytical institutes might then feel constrained to follow their example

The Liverpool Regional Hospital Board is to be congratulated on bringing out a well-printed booklet giving preliminary information about the hospital and specialists services provided by the Board This contains a map showing the position of all the hospitals supervised by the Board, and details are given of the 19 hospital management committees in the area The public and the medical practitioners in the Liverpool hospital region are told that it is not the Board's intention to bring about immediate sweeping reforms, in general they may expect to obtain their hospital services after the appointed day as they did before Useful information is included about how the admission of patients both to general and to special hospitals should be arranged, and the method of obtaining pay-beds is described Of particular value is the section on mental health services This makes the new procedure of reception into a mental hospital appear simple In the near future it is hoped to establish an emergency bed bureau service and to circulate among the practitioners in the area the names of those specialists who are prepared to undertake domiciliary consultations

## Correspondence

### Diabetic Coma

SIR,—We have read Professor R. H. Micks's article (July 24, p. 200) on diabetic coma and there are several points on which we must disagree. It is not true that all America agrees that the giving of glucose early in diabetic coma is dangerous and prevents recovery, a point of view advocated by Dr. Root at Dr. Joslin's Clinic in Boston and supported by Professor Micks. What we are chiefly concerned with, however, is his advice to everyone, practitioners included, to give enormous frequent doses of insulin even in cases of what we call 'pre coma'. We shall show that this is unnecessary and must involve the risk of grave hypoglycaemia.

Professor Micks does not give details of a single case to show how his theory works in practice, but we must quote some of his suggestions without taking them unfairly out of their context. If the patient can give a clear account of himself or is only "drowsy and confused" (hardly even pre-comatose) he should be given 100 units at first which should produce "an obvious improvement" in 15 minutes. In our experience a subcutaneous injection of insulin never shows any effect in 15 minutes even in the mildest diabetic. Again, "in an early case, if there is no obvious improvement in half an hour, give 100 units every half-hour until improvement is obvious"—i.e., probably many hundreds of units. We consider this unnecessary and dangerous.

The accompanying table shows four-hourly insulin dosage and blood sugars in three typical severe cases of pre-coma treated during the past year. In each case the patient could only be roused with difficulty and was therefore in a more advanced pre-comatose state than that suggested by Professor Micks's description quoted above. The total amounts of insulin required to remove the ketosis, control the blood sugar, and restore the patient to full consciousness were 124, 142, and 196 units respectively.

Hours	Case 1		Case 2		Case 3	
	Insulin	Blood Sugar	Insulin	Blood Sugar	Insulin	Blood Sugar
0	80	665 mg %	60	800 mg %	40	500 mg %
4	12	256	20	572	40	512
8	12	200	30	500	32	280
12	12*	222	24	—	40	214
16	8	143	8	—	20*	125
20	0	106	0	200	12	145
24	—	—	0*	256	12	167

\* Ketosis disappearing

It is obvious that hundreds of units were unnecessary and would probably have produced grave hypoglycaemia—difficult to combat, we find, when vast depots of injected insulin still remain potent. We should add that we have not lost a case of so-called coma of this type for years.

The occasional case, now rarely seen by us, of profound coma with *circulatory collapse* is quite different, as also is our treatment of it. We give hundreds of units of insulin but only when we find that the first big dose has had no effect in reducing the blood sugar in 4 hours, taking into account the slight blood-sugar dilution caused by liberal intravenous saline. We press these big doses rather empirically, thinking that owing to circulatory collapse most of this insulin is wasted and ineffective. Occasionally such patients die in spite of enormous doses of insulin and removal of ketosis because of failure to maintain an adequate circulation. This situation is quite different from the mild type mainly described by Professor Micks where hundreds of units in our opinion, are both unnecessary and dangerous.—We are, etc.,

### Use and Abuse of Tonsillectomy

SIR—It would never do for anyone in authority to implement the opinion expressed by Dr. H. Stanley Banks at the Preventive Medicine Section of the Annual Meeting of the British Medical Association (July 17, p. 161) that the prohibition of tonsillectomy during epidemics (of poliomyelitis) is the only useful administrative measure of control (against the disease). But Dr. Banks's pronouncement is an important and a valuable one. Here is a well-known physician, a leader in his branch of medicine, who wants temporarily to stop all removal of tonsils during a time when some disease is prevalent that seems to him of greater importance. His opinion sounds like a challenge to Mr. V. E. Negus, speaking in another section on the same subject, to produce his evidence of the "various troubles caused by not doing the operation" until the epidemic is passed.

Let us see where such an order might lead us to. Poliomyelitis is not the only disease to which it might be applied. The post-tonsillectomy measles mastoid is so deadly that to take out tonsils during an epidemic of measles from a child who has not had the disease is as risky as to do so during an epidemic of poliomyelitis. Then were such an order made I should demand that it be extended to all such operations during the winter months and should have behind me the support of many leading physicians. I have applied the principle of cessation of tonsil operations during winter months and during measles epidemics for twenty years and have never seen any trouble arising from the delay. But if temporary cessations seasonal and epidemiological, of tonsillectomy are much to be desired, why should not the administrative fiat be extended to the whole host of tonsils that has been going on for a quarter of a century? It might be ordered that none should be removed under the age of nine, and then only for indications that could not be exceeded. No! Salutary as such orders would be in many ways, we cannot conduct the art of medicine by administrative fiat, and this part of the art must be amended by two other methods.

The first is that the profession as a whole should reconsider its approach to tonsillectomy. Practically every experienced physician in the land deprecates its excessive frequency. The Ministry of Education has short of dictation, done all it can to limit the number arising from its school inspections. Yet still it goes on to such an extent that it can only be explained as being due to a disharmony of the human mind. Future generations will, I believe, wonder and some may laugh at our propensity to it, just as we do at the bleeding and purging of the end of the eighteenth and beginning of the last century.

The other is that parents should again assume the responsibility for decision that they have so long laid aside. The doctor does not order, he advises. If parents would say, "No, I will not have my child operated on until the epidemic is over (or until the winter is past)" they would find that the child is none the worse for the delay and often that it has entirely recovered from the symptoms for which the operation was originally advised. The reassumption of their responsibility might thus lead inquiring minds to demand more from the doctors who advise this operation than they have in the past and this in turn might ensure the profession as a whole making that reconsideration that seems so necessary.—I am, etc.

T. B. LAYTON

### Renal Complications in Diabetes Mellitus

SIR—We would like to make a comment on the interesting article on renal complications in diabetes mellitus by Drs. W. R. Gauld, A. L. Stalker, and A. Lyall (July 24, p. 194). They admit, and we agree, that there is no certain way of distinguishing during life between intercapillary glomerulosclerosis and subacute nephritis (we should prefer to say Type II nephritis). Having found one case (No. 13) in which the typical lesions of Kimmelstiel and Wilson were not found at necropsy, they create a new group of three cases of "subacute nephritis" complicating diabetes, although in the other two cases there has been no necropsy evidence. The only criterion used by them in putting the other cases into this group seems to be the of the patients.

It is wrong to assume that intercapillary glomerulosclerosis is only found in the elderly. In our present series of 16 cases (9 with necropsy confirmation) we have patients aged 47, 42, 31, 40, 42, 39 and 33. The first three of these have died and the characteristic lesion has been found. The 31-year-old patient had had diabetes for 21 years. Most of these cases have been seen by us through the courtesy of Professor T. H. Oliver, at whose diabetic clinic they have attended.—We are, etc

### Prevention of Dust Diseases of the Lung

SIR—Dr Leonard W. Hearn says (July 17, p. 172) that grit and dust particles cannot be inhaled through a simple butter muslin or gauze mask and suggests that all workers under dusty conditions could be assured of protection against pneumoconiosis if they wore such a mask at work.

Mr R. F. Hounam of the Pneumoconiosis Research Unit investigated the filter efficiency of a simple gauze and cotton wool mask that is produced commercially as a dust respirator and found the following results for coal dust clouds

Particle Size	% of Particles Penetrating Mask
5 $\mu$	30%
2 $\mu$	70%
1 $\mu$	90%
0.5 $\mu$	95%

Since it is generally agreed that small particles particularly those of 2  $\mu$  and under, are chiefly responsible for producing pulmonary fibrosis when inhaled it may be concluded that simple gauze masks would be ineffective in the prevention of pneumoconiosis.

Members of the scientific staff of the Chemical Defence Experimental Establishment are at present collaborating with members of the scientific staff of the Pneumoconiosis Research Unit in the design of a simple but effective filter-pad to cover the mouth and nose which could be discarded after use for a single shift and which should be wearable without discomfort. A pilot model of this mask is nearly ready for trial. However, even if this simple mask is found to be wearable and effective in practice we should not like to suggest that its use should supplant dust suppression in the prevention of pneumoconiosis. I have recently seen a miner who developed advanced silicosis after only six years' work drilling in rock, during the whole of which period he wore a Mark IV respirator at work. This mask in the laboratory is at least 95% effective for particles above 0.2  $\mu$ , but it is clearly not always effective in use. My plea was for "effective" action directed to prevention and aftercare in the problem of pneumoconiosis. In such action the provision of dust respirators will only play a small part.—I am, etc

Pneumoconiosis Research Unit  
Llanoughor Hospital  
Nr. Cardiff

C. M. FLETCHER

SIR—The letter written by Dr Leonard W. Hearn (July 17, p. 172) is of very great interest to those of us who have spent many years in the mining areas and whose work has been more or less limited to the x-ray examination of miners' lungs. Dr Hearn is 'lost in wonder that no mention is made of the simple and sure means of prevention and protection by the use of the small pad indicated by him. We also are lost in wonder that Dr Hearn did not at some time or other make known many years ago this "simple and sure means" and thus have saved not only the lives of colliery workmen and the misery and anxiety connected with deaths due to dust disease but also saved millions of pounds together with many hours of anxious work and research which have apparently been thrown down the drain by simple-minded people in the mining areas.

On whose authority does Dr Hearn state that the muslin pad is a 'simple and sure means of prevention'? We have failed to find any evidence of work which proves that there is 'a simple and sure means of prevention and protection in dust diseases of the lung'. No one has ever suggested that 'grit can be inhaled' but we are at a loss to know exactly what he means by 'dust particles' as this term is, to say the least, very indefinite.

Many years ago one of us (A. H.) carried out experiments with various types of mask, and by a mask we mean a mask, and not merely "six folds of butter muslin" and watched over several years the effect of these masks including the Mk IV so kindly given to him for that purpose by the late Professor David Jones, who assured him that dust particles of 5  $\mu$  or less would not pass through this latter type. The filtering properties of "six folds of butter muslin" cannot in any way be compared to the filters used in the Mk IV mask. This tends to show that Dr Hearn has rushed in where others fear to tread as the results obtained controlled by x-ray examination for a number of years showed that the various masks were useless as the usual proportion of patients still died from lung disease due to dust inhalation which was proved on post-mortem examination.

Very many years ago we stated that x-ray examination of all entrants to the coal mining industry should be compulsory, and that periodic x-ray examinations of these men should be carried out so that on the earliest harmful evidence of pneumoconiosis the men should be given some other type of work away from all dust dangers. It would seem to us that, until the Medical Research Council or any other responsible persons publish evidence to the contrary this is the only "simple and sure means of prevention and protection" or until the mining engineer can eliminate "dusts" from colliery workings. Masks of various types and masks of varying degrees of uselessness are to be found on the scrap heap in any mining area where dust disease is prevalent.—We are, etc,

Ammanford Colliery

### Service Doctors in Far East

SIR—The letter from Lieut. D. R. Morgan, R.A.M.C. (July 3, p. 54), complaining about the treatment of married non-regular officers in FARELF, is based on a misunderstanding of the regulations governing the grant of family passages. Owing to the shortage of quarters a points system was introduced, which was thought to be fair to all irrespective of age and rank. Married officers and men with the longest separation from their families were given the most points. The non-regular or National Service man with a total of two years to serve, and most likely not more than eighteen months overseas, is unlikely to acquire sufficient qualifying points. Families are not moved unless quarters are available, and unless the husband has at least one year's service to complete before being due to return to the United Kingdom. There are many regular officers who have had to serve their full term of three years overseas without acquiring sufficient points for their families to join them. There is no United Kingdom leave for any soldier during his three years overseas duty tour, except for soldiers in Europe.

Lieut. Morgan appears to feel there is some discrimination between regulars and non-regulars but both in estimating the points system and in the payment of local allowances and of marriage allowance. National Service men and regular soldiers are on the same footing. A married officer who is not living with his wife and family cannot expect to receive local allowances at the rate of a married officer accompanied by his family as he is already receiving marriage allowance at United Kingdom rates and is allowed overseas allowances for himself at single rates. The half-rate marriage allowance of officers under 25 is the same for both regular and non-regular and is not peculiar to FARELF, it applies everywhere.—I am, etc

The War Office

### Golden Jubilee of the R.A.M.C.

SIR—All will be gratified at the graceful acknowledgment by Major-General R. E. Barnsley (July 24, p. 223) of the decisive and successful action by the B.M.A. from 1896 to 1898 recorded in your leading article of June 26 (p. 1242) and commented on by Dr W. C. Souter (July 10, p. 107) which resulted in the long-overdue establishment of the Army Medical Corps. As an addendum I would, however, remind him that no account of the detail of this outstanding piece of work can be considered complete if it omits honourable mention of the

work of the late Dr W Gordon, of Exeter, who at that time was secretary of the South-Western Branch of the Association. Such was the strong line he took within the Parliamentary Bills Committee on the subject of reform of the Army Medical Service that a special subcommittee was formed, and a letter from him as chairman of this subcommittee was addressed to the Secretary of State for War (Lord Lansdowne), afterwards published.<sup>1</sup> Later in 1896 'the elaborate and able memorandum' on the subject by the subcommittee's chairman is referred to in the proceedings of the Parliamentary Bills Committee and the report itself was published.<sup>2</sup> Eventually, early in 1898 a highly authoritative deputation was well received by Lord Lansdowne.<sup>3</sup>

It is of course not recorded in the minutes, but it is within my knowledge privately from Dr Gordon, that Lord Lansdowne, before coming to his final and favourable conclusion, sought a further interview (which was a prolonged one) with Dr Gordon as chairman of the subcommittee. Such ability and energy had he exhibited in the conduct of this matter that at the succeeding Annual Meeting he was awarded the thanks of the whole Association on the success of his efforts. It is appropriate that at this moment these facts be again put on record, but a full account will be found in the BMA's *Annual Handbook* of 1921-2, which contains a special historical section, and in E Muirhead Little's *History of the BMA* p 153, *et seq*—I am etc

## Lower-segment Caesarean Section

SIR,—As the author, in 1933, of the use of Willett's forceps in lower segment caesarean section I must strongly demur to Professor F J Browne's condemnation of them (July 10 p 105). I have so employed them for the last 16 years and have never occasioned injury to the child's scalp beyond, in about one case in three, a small swelling underneath it, which is almost certainly mostly serum for there is rarely any bruising and which disappears in a week or two. They were not advocated for violent traction on the head but only a pulling sufficient to keep it against the uterine incision and prevent bleeding from its edges. Forceful clumsiness no doubt makes them a barbarous instrument but the barbarity is in the operator's hands and not in the forceps. I generally have two and sometimes three on at the same time, and this diminishes the force brought to bear because it is distributed over a larger area. Meanwhile the uterine incision is enlarged until it is big enough to let the head slip out. The advantage of the forceps is that they permit of traction on the head while the uterine incision is still small, and this much reduces the amount of bleeding. Sepsis such as Professor Browne describes argues a failure of aseptic technique by someone during or after the operation—I am, etc

VICTOR BONNEY

## Whooping-cough and Measles

SIR—There has recently been an outbreak of whooping-cough and of measles at an orphanage to which I have the honour to be medical officer. The children were isolated in two wards for the separate diseases but five whooping cough cases (aged 4-8, with duration of from 7-14 days' actual whooping and vomiting) subsequently developed measles in addition.

The first child so infected became acutely ill with bronchopneumonia, and to relieve the overworked staff I got him admitted to the local isolation hospital. The remaining four after the usual few days' discomfort of measles, made uninterrupted recoveries, with this interesting difference. From the second or third days from the appearance of the rash they entirely lost their spasms nor have they had further attacks although now up and about. The bronchopneumonia child had no spasms when in hospital, although he had been whooping and vomiting strongly before going. The whoops may have been missed in the general chest condition but the matron was inclined to think he had "not been suffering from whooping-cough at all" until I told her about the others.

Are these five cases merely coincidences or is there any known medical reason why an added measles should have apparently "cured" these distressing spasms so quickly? Mixed cases of this type must be rare and I do not remember one before in twenty-three years—I am, etc

Malmesbury Wilts

B L HODGE

## Acute Intussusception in Childhood

SIR—DRS Brenda Morrison and Donald Court are to be congratulated on their very interesting and instructive paper on this subject (April 24, p 776). They have given a very full, accurate, and detailed description of the common signs and symptoms of this disease.

They found that fever was more commonly associated with intussusception than was usually believed to be the case. I believe, however, that the temperature is of no diagnostic significance. Also they found that the passage of blood per rectum was absent in 24% of their cases, and that 30% passed some blood within the first twelve hours. In my experience the passage of blood per rectum has been absent in some cases where the intussusception commenced in the terminal ileum within six to ten inches of the ileo caecal valve, and these are the cases which soon become irreducible. With regard to the early diagnosis they stress the importance of a personal interview with the mother of the infant. Few cases would be missed if the doctor would listen carefully to the history of the child's illness as given by the mother, who is such an accurate and close observer where her infant's health is concerned. She notices the sudden onset of the illness, the pallor and sweating due to shock, the recurring spasms due to pain, and lastly, when it occurs, the passage of blood. With regard to the presence of a palpable abdominal tumour, this may be difficult to palpate, but there must be few if any cases where such a tumour cannot be palpated either with or without an anaesthetic.

With regard to treatment, the problem of reducing an intussusception is very similar to that where the reduction of a hernia is concerned, in that some reduce very readily and others soon become strangulated, and the duration of the trouble is not always the principal factor determining the possibility of reduction. Some will reduce easily after several days and others become irreducible within a few hours. It has been my experience after systematically attempting reduction of intussusceptions by hydrostatic pressure, using a column of saline or water from a height of three feet six inches that over 60% of all cases presenting themselves for treatment become reduced if the pressure is maintained for eight minutes. After using this method over the last 35 years in several hundred cases I am convinced that it should always be given a trial.

Mr Ralph H Gardiner (May 22, p 999) states that he regards the method of what he calls the "use of pressure enemata" as an extremely dangerous procedure, one of his reasons being the impossibility of telling whether the intussusception has been completely reduced. I know that this is also the opinion of many other surgeons. I feel sure, however, that both Mr Gardiner and these many others have never given this method a proper trial. The method is simple, safe, and effective in most cases, and in over 40% of all cases presenting themselves for treatment one can be quite sure that reduction has been effected, although in 18% of those reduced an operation to confirm this fact should be done. If all cases are operated upon then at least 40% will be operated upon unnecessarily.

The principal sign indicating complete reduction is distension of the abdomen when no such distension of the abdomen was present before the injection was used. The distension is due to some of the saline passing through the ileo caecal sphincter into the small bowel. It was after using thin barium enemata many years ago to bring about reduction, and then taking an x ray when I observed that in many cases the opaque solution had passed into the small bowel. As this brought about an even distension of the abdomen where before the injection was given the abdomen was soft and flaccid, I came to the conclusion that it was better to use hydrostatic pressure in a room adjoining the operating theatre and with the child prepared for an operation, so that no time would be wasted if one decided that an operation was necessary. I may state that in no case since using this method over the last 35 years have I made the mistake of sending the child back to the ward as having had the intussusception reduced when such was not the case—I am, etc.

## Dietary Deficiencies

Although there seems to be no evidence of severe malnutrition in this country at the present time, there are, in individual cases manifestations such as lack of concentration, lassitude, chronic fatigue and nervous disorders which appear to be caused by inadequate diets. Some of these symptoms may be signs of a deficiency of the B vitamins.

Marmite is a yeast extract containing naturally-occurring riboflavin (15 mg per oz) and niacin (165 mg per oz) as well as other factors of the B<sub>2</sub> group derived from yeast, these include pyridoxin, pantothenic acid, choline, biotin and folic acid.

The dietetic value of Marmite has long been recognised; it is prescribed extensively as a prophylactic measure in combating malnutrition.

## A woman with an intimate problem . . .

The question of whether or not to use internally worn sanitary protection is one which all women face sooner or later. In doing so, they naturally seek the guidance of one whose advice they completely trust—that of their Doctor. Tampax, which was invented by a gynaecologist and has already been accepted by thousands of members of the Medical Profession throughout the world, deserves your endorsement for its assurance of hygiene, physical comfort and alleviation of mental strain. If you are not acquainted with Tampax, descriptive literature and samples of both absorbency sizes will gladly be sent on request.

★ Tampax may be confidently recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenial aperture would cause difficulty in insertion and withdrawal.

### Comprehensive Child Health Service

SIR—I was very interested to read the suggestions put forward by Dr P O Crossfield (July 24 p 227) for a comprehensive child health service. I agree with him completely in all he says, and Dr Crossfield may be interested to learn that I am attempting as an experiment and in a very modest way to provide such a combined preventive and curative child health service such as he describes.

It is obviously illogical to have one set of doctors concerned with child health and another with child disease. If one counts up the possible number of different doctors a child may see between birth and school leaving age it is small wonder that parents receive so much conflicting, or apparently conflicting, advice. The problem of combining the two sides of paediatrics will have to be faced soon and at the moment all that seems to have been done is a vague suggestion that general practitioners should conduct infant welfare clinics from health centres. Will each doctor see those children registered with him or will he see those of his less enthusiastic colleagues as well? If the latter, will the doctor with whom a child is registered have no objection to his patient being seen by another doctor?

I cannot see how the general practitioner working under modern conditions can possibly have time to conduct infant welfare clinics for his babies and carry out annual routine examinations of his children, and if he keeps his practice small enough to allow for this service I would then say that he was not seeing a sufficient number of children to keep experienced.

I am watching with interest to see the effect of the National Health Service on the care of children. School clinics and children's hospital out-patient departments are said to be expecting an unprecedented rush shortly as harassed GPs refer children for treatment they have not time to administer themselves. If this does in fact happen, then there would be sound reason for setting up a service such as that described by Dr Crossfield.

We shall no doubt be criticized for breaking up the concept of the family doctor and for attempting to cut out yet another section of general practice. If the paediatrician visits the children in their own homes when they are ill he will soon become aware of the child's social background just as much as though he were the mother's own medical attendant, and if he works in close co-operation with the mother's doctor, say from the same health centre, then the first criticism will no longer be valid.

Rather than this scheme should be regarded as the excision of the care of children from general practice, I prefer to regard it as an attempt to grab back to general practice the work that has been done by public health authorities, but with the difference that some general practitioners should devote themselves wholly or in considerable part to the care of children only. I thus prefer the term general practitioner paediatrician, because in my scheme he would not be a substitute for the consultant paediatrician who would still be needed for difficult cases but much of whose work could be done by the general practitioner paediatrician with his superior experience over the ordinary doctor.

The criticisms often levelled against semi-specialism in general practice are not so relevant against paediatrics because the narrowing influence that work with one organ or one system of the body may have on a man is not present. Paediatrics involves a wide field of medicine, preventive and curative applied to a certain age group, but it is a study nevertheless that makes specific demands upon its devotees justifying separation from the rest of medicine.

Children have already been a cause of an unforeseen difficulty in the National Health Service to judge from the reports of doctors who have refused to take them on. We may deplore this behaviour as unethical but there is no doubt that children require extra care and few in the younger age groups can go through a year without requiring several items of service. Therefore if a scheme such as Dr Crossfield and I have outlined is to attract adherents it is a necessary corollary that there should be a higher capitation fee for children not only to compensate for the extra susceptibility that children have to illness but also to pay for the purely preventive services—I am, etc.

FRANK J.

NORMAN J. COOK

SIR—May I support and extend Dr P O Crossfield's admirable suggestion (July 24 p 227) that every community should have its community paediatrician with all the children of the area 'from almost conception to 12 years on his panel? Why stop here? It is well known that the years of adolescence

have their special problems. I propose an extension of Dr Crossfield's plan on their twelfth birthdays let all the children be transferred to the panel of a specialist for adolescents. At 20 or earlier if events necessitate it they should of course transfer again to the list of a specialist in all that pertains to the reproductive period. Possibly for this phase there should be one specialist for each sex. The climatologist and the gynaecologist, assuming control in their turns would complete the scheme.

Dr Crossfield mentions the GP in passing. As my logical extension of his plan eliminates the need for GPs to do anything but allot patients to their age groups they may as well be abolished altogether—and with them their crazy notions about continuity of treatment and the family as the clinical unit. "The advantages are obvious, the opportunity unique"—I am, etc.,

Cambridge

H R YOUNGMAN

### Globin Insulin

SIR—The warning expressed in the leading article entitled 'Modern Views on Diabetes' (July 24, p 209) against the danger of over-simplification in the treatment of diabetes is welcome. Dr G M Wauchope (p 191) seems to advocate a single, morning dose of globin insulin because of simplicity of administration. As you point out however the action of a single, morning injection of globin insulin is generally too short to control the fasting blood sugar. This is in fact well illustrated in Case 21 in Dr Wauchope's paper although one must grant that she has been surprisingly fortunate with her results in others.

When insulin is required it is certainly desirable to restrict its administration to a single dose in the day whenever possible. I have almost abandoned the use of globin insulin for this purpose in the average case as in my experience very much better control can be effected with a mixture of soluble and protamine zinc insulins. Two parts of soluble with one part of protamine zinc insulin mixed in the syringe is most generally useful, but the proportions have to be adjusted to individual requirements. Unlike Dr Wauchope, I do not find any difficulty with this method. A few cases are encountered who cannot be controlled with a single dose and would require three or four doses of soluble insulin per day. In view of my experience of the brief action of globin insulin I have tried this insulin in a number of such cases, giving morning and evening injections, and have found this gives satisfactory results. But these cases are exceptional.

Your other advice, that "the carbohydrate content of the diet, however large should be kept relatively constant" is also important if proper control is to be obtained. Yet Dr Wauchope describes her typical case as eating "mountains" (an uncertain measure) of bread and potatoes, and she 'supposes' the little child John is on a free diet. However, she seems to find some dietary instructions necessary, as serious results overtook her patient who omitted his "mid-morning lunch". A suitable insulin mixture in place of globin insulin might overcome the necessity for such additional meals—I am, etc.

IAN MURRAY

### Confidential VD Treatment

SIR—For over 30 years treatment of VD in this country has been confidential by custom and by statute. The effect of this, together with the arrangements for free voluntary treatment and careful public education has been excellent as the figures of attendance at public clinics show. The certainty that confidence will be kept by all concerned in the treatment medically and administratively is one of the main factors in inducing the early and continued attendance of persons who have—or think they have—contracted VD. The personal troubles and family complications of such persons are in the majority of cases acute and the disease usually has social and moral implications which are fortunately not attached in the same degree to other diseases.

The Minister of Health has, in the course of necessary re-arrangements for the working of the National Health Service Act revoked the 1916 Public Health VD regulations one clause of which made this requirement of confidence statutory

to be noted is that the other guiding principles in the amendment—that it shall be free, and that it shall be voluntary—which were secured under the 1916 regulations are dropped in the new scheme. But the important and necessary element of confidence on which all British V.D. treatment has been built and on which all public propaganda is based is deliberately left out. No explanation has been given, nor have any satisfactory replies to Parliamentary and other questions been received.

The Minister has stated that he hopes confidence will be maintained as before, and no doubt doctors, nurses, administrators, etc., will do everything possible to observe this as in the past, but his hopes cannot have the same power and efficacy as a legal requirement. The Amendments to the NHS Act which are now being drafted will presumably rectify the omissions and ambiguities of the Act. It is to be hoped that the medical profession, and all who are concerned with the treatment of patients and administration of clinics and hospitals, will urge the Minister to restore the requirement that (to quote the 1916 revoked regulation) "all information obtained in regard to any person treated under a scheme approved in pursuance of this article shall be regarded as confidential."

The public and the medical profession are already sufficiently troubled about the incidence of V.D. Why should the Minister remove, and apparently be unwilling to restore, this essential feature of our British system of V.D. treatment, which is an encouragement to sufferers to come for help and medical care, some protection to the medical profession and administrators in their difficult tasks in this field and is admirably suited to our British constitution and character?—I am, etc.,

KATHARINE B. HARDWICK  
General Secretary

Association for Moral and Social Hygiene

### Colonial Medical Service

SIR—Many correspondents from many Colonial territories have drawn attention in your columns to the shortcomings of the Colonial Medical Service. It is indeed true that the pay is meagre, the equipment and administration deplorable, and the supply of drugs and doctors pitifully inadequate. It is also true that the Service contains a number of first-class men who have made, and are making, fine contributions to scientific knowledge and that there is a wonderfully interesting job to be done in the Colonies.

After the war a number of men joined the Service who had gained considerable experience in medicine, surgery and administration. This transfusion of new blood should be capable of reviving the patient, but alas it seems more likely to be haemolysed into premature resignation in disgust. The Colonial Medical Service has only too often lost the services of its ablest young men, and urgent action is necessary if this process is not to be repeated on a larger scale. For this state of affairs the laziness and inefficiency of some of the senior officers in the Service must share the blame with the disregard of Colonial Governors for medical and health matters.

I therefore beg, Sir, that the B.M.A. will give a lead to those members of the Service who believe that it is better to fight for a better service from within rather than to shake the dust from their feet. I suggest that the Association should take urgent action upon the following lines:

(1) Organize all B.M.A. members in the Colonial Medical Service into a strong and active branch of the Association.

(2) Bring pressure on the British Government to set up a Royal Commission to investigate medical services in the Crown Colonies, and to recommend reforms.

(3) Bring pressure on the Government to divert a proportion of national service doctors to the Colonies for their term of conscript service as an alternative to the armed Forces.

(4) Failing effective action by the Government within six months the B.M.A. should set up its own committee of inquiry on the Service and decide whether Association members should be recommended to resign from the Service and be deterred from joining it.

I suggest, Sir, that with strong action on these lines we could rapidly build up a Colonial Medical Service second to none, in which it would be regarded as a privilege to serve. The matter is urgent, for even the inarticulate peoples of the Colonies are beginning to realize that they are not getting the medical services they need, and to say so in no uncertain terms—I am, etc.,

Moretonhampstead, Devon

IMPERIALIST

### Night Thoughts

SIR—I forward these notes in the belief that they may be of some assistance to fellow practitioners who are engaged in general practice in the present Utopian era. At 10.45 p.m. on the third day of Utopia I was called to a lady who was violent, manic and possessed of systematized delusions of persecution directed against her husband. She could not be brought under control by ordinary means and spent her time either rushing wildly round the house in search of lethal weapons with which to dispatch him or creeping stealthily round his room at keyholes.

The first telephone call I made was to a colleague, requesting him to come in order that we might certify her. The second was to the home of a local J.P., but there was no reply. The third was to the gentleman who had until July 5 acted in the capacity of the Relieving Officer, but again there was no reply. When my colleague had arrived and we had seen the patient and discussed the case, we put through the fourth telephone call, this time to the local police, requesting their co-operation in locating the late Relieving Officer. The police sent a car to his house and found no one at home.

Meanwhile Dr. C. rang up the Blantyre County Mental Hospital and was informed that though the patient resided in Blantyre she had no jurisdiction since July 5, and advised him to contact the Area Regional Board, the telephone number of which was not known to them. The sixth call was made to Directory Inquiries, who replied that they had a list of hospitals but no number for the Area Regional Board. The seventh call was made to the mental hospital to which the patient had been admitted previously, but they under the new scheme were not permitted to readmit her. The eighth was to the convalescent hospital to which she had previously been discharged but no information could be obtained from them.

A police sergeant and constable then arrived to inform us of the result of their attempts to find the Relieving Officer, and when I suggested that they should assist while I tackled the patient, she gave her an injection. The sergeant replied that it was more than a job was worth. He did agree, however, to send a message to the County Police Headquarters asking for information. That was the ninth telephone call. It was then 3.30 a.m. and I decided that it was time something definite was done. I therefore rang the Ministry of Health and had a very pleasant conversation with the night operator there. He knew of no medical man in the building, but put me in touch with the duty officer. The duty officer agreed, when I explained the position, that things were a bit difficult and promised to make inquiries. County Police Headquarters then rang up to say that they had located the late Relieving Officer, who had told them it was nothing to do with him.

I was then rung up by an unknown who said he was sorry to do with the Board of Control and had been approached by the Ministry of Health and told to communicate with me. He apologized for his inability to quote chapter and verse, owing to the fact that he had not got his files in bed with him, but assured that it was not the Relieving Officer with whom I ought to get in touch but the Duty Authorized Officer, adding, "He is usually a man who used to be the Relieving Officer."

From him I did succeed in extracting the names of all the mental hospitals in the Region, so that my eleventh call was directed to one of these. The night porter was sympathetic but explained that it was impossible to rouse any of the doctors at that hour, and when I rang again in the morning. The twelfth was to Directory Inquiries to obtain the telephone number of another mental hospital, but I was unable to find in the directory. The operator was also unable to find it.

My friend the late Relieving Officer then rang up to ask why I kept sending the police to disturb him and didn't we know that he had retired last Friday? After pacifying him I extracted the name of the Duty Authorized Officer for the area from him, and put through my thirteenth call. The Duty Authorized Officer told me that the best thing to do would be to ring up the County Hospital at Bungwell, the telephone number of which was Pingpong 2286, and see if they would help. The fourteenth call, to Pingpong 2286, produced no reply. My fifteenth call was to Directory Inquiries, who were unable to find any mention of the County Hospital at Bungwell.

My sixteenth call, to the Duty Authorized Officer, never got through, for the local operator interrupted to say that his Agatha once went nuts and was sent to the County Hospital at Bungwell, but they called it St. Bernard's. He had overheard, unintentionally, my chat with Directory Inquiries, and had the liberty of looking it up in the Directory. The number was Pingpong 2256. So my seventeenth call was to Pingpong 2256. The night porter was very kind. He explained the local arrangement of telephone lines, which was so organized that though he could not get the doctor on duty should it be necessary to rouse him, I could not. I thanked him politely and requested him to rouse the duty officer. Thus he did and the ensuing relayed conversation was incomprehensible.

My eighteenth call was to the Duty Authorized Officer who made the suggestion that if I failed to get any satisfaction from the Mental Hospital at Hungwell, Pongping 3392 he would willingly rise from his couch and come along in person. My nineteenth call to Pongping 3392 was most edifying. I was connected almost at once with the duty officer and poured out my tale of woe. But alas, the duty officer was deaf, and not merely deaf but had only a slight knowledge of the English language.

In disgust I put through my twentieth call to disturb the poor Duty Authorized Officer who, some forty minutes later, preceded by ten minutes by an ambulance with the necessary attendants, arrived in person. I looked out of the window and admired the effect of the long shadows cast by the rising sun while the Duty Authorized Officer refreshed himself with a strong whisky and soda, and I turned in dismay as I heard him explain to Dr C that he hadn't got the necessary forms. It appears that he had not yet received his supplies of these essential commodities. We therefore did what was necessary in manuscript, and saw the patient safely inside the ambulance.

And as I drove home to get a shave and a quick breakfast before starting my morning surgery I thought of the blessings bestowed upon the medical profession by Saint Aneurin Bevan, whose self confessed aim is an eight-hour day five-day week for doctors—I am etc

PRIVATE PRACTITIONER

## POINTS FROM LETTERS

### Pain in Childbirth

Dr J S LAURIE (Pontefract) writes. Certain remarks in recent correspondence on pain in childbirth prompt me to suggest one simple but effective method of dealing with one of the main aspects of the problem, namely the fear of the unknown. I am aware that my procedure is by no means unique, but equally it is not practised nearly as widely as might be. As medical officer to an ante-natal clinic I hold a short talk at three monthly intervals and during a clinic session. It is illustrated by wall charts, black-board diagrams, and home made plasticine models. Every woman should have at least two opportunities to attend, and although mainly intended for primiparae I find quite a large number of multiparae interested. I describe briefly and in basic English the process and meaning of menstruation, the process of gestation, with the formation of placenta, cord membranes, and liquor, and their function. I stress the slow process of taking up and dilatation of the cervix in labour and the importance of relaxation and calm during this phase to avoid exhaustion when effort is finally required, and I warn against horrific old wives' tales. A final word about immunization and vaccination and a warning against the use of purgatives in infants winds up a total of about twenty minutes, during which my small audience is obviously intensely interested. These talks have been going on for about two years now and the results have been most gratifying: the mothers appreciate the process of labour and really do try to co-operate with very good results.

### Vaccination

Dr J B GURNEY SMITH (Epsom) writes. I was interested in Mr W K Fitch's remarks on this subject (July 17, p 177). When I served in the Royal Navy in the recent war we sometimes arrived at ports where smallpox was then prevalent. Port orders were usually received on board on our arrival to state that no naval personnel were to be allowed ashore unless they had been successfully vaccinated. I gather by successful vaccination it was meant that the individual showed a vigorous cutaneous reaction. Surely successful vaccination should imply no reaction at all and therefore no susceptibility to the incidence of smallpox. I feel the phrase "successful vaccination" is an unfortunate one and in the same category as Mr Fitch's remarks on "take".

### Herpes Zoster and Chicken pox

Dr A SCOTT SMITH (Haydon Bridge, Northumberland) writes. I recently visited three children of a family who were found to be suffering from varicella. On the following day the grandfather of the children came to see me complaining of pain in the left leg which he said was "herpes zoster". On examination I found that he had a large patch extending from the sciatic notch to the popliteal fossa. The grandfather lives at an isolated place about two miles from his grandchildren and is visited weekly by the father of the children. He had not seen his grandchildren during the past three months and had not been in contact with any cases of chicken pox. Presumably the father was the carrier. The initial pain in the leg was felt two weeks after the children developed chicken pox. The severe herpes zoster pain responded quickly to treatment with paracetamol over-extracted, as first described by Dr Hugh Dickie in the *Journal* of June 15, 1946 (p 942) and by Dr James Kay (July 6 1946 p 28).

## Obituary

### DAME AGNES HUNT

Dame Agnes Hunt, founder of the Shropshire Orthopaedic Hospital which is now known as the Robert Jones and Agnes Hunt Orthopaedic Hospital Oswestry, and of the Derwen Cripples Training College died at her home at Baschurch, Shropshire on Saturday July 24 at the age of 81.

Agnes Gwendoline Hunt one of the younger members of the large family of a Shropshire squire Rowland Hunt of Boreatton, was born in 1867. Though a cripple herself she trained as a nurse in the Royal Alexandra Hospital Rhyl and in the Salop Infirmary. She was a district nurse for 11 years and then in 1900 she started an open air hospital in an old house in her native village of Baschurch. Starting with subscriptions and donations amounting to £132 she finally created not only a hospital dealing with hundreds of patients but a complete organization for the aftercare of cripples in Shropshire and the Midlands. During the 1914-18 war soldiers were taken as patients and Dame Agnes then became commandant of the Auxiliary Orthopaedic Hospital at Baschurch.

Mr G R Girdlestone writes. Dame Agnes Hunt has left this troubled world after many years of the most strenuous and beneficent activity carried through in spite of or perhaps because of, almost constant pain and severe disablement. About 65 years ago the family doctor had found her one morning in extreme distress after a sleepless night of pain and misery since it meant the loss of an eagerly anticipated picnic in the hills. With kindly insight he talked of his own experiences so that she began to share his sympathies, then wrote these lines in her birthday book.

'Reared in suffering thou shalt know  
How to solace others' woe  
The reward of pain doth lie  
In the gift of sympathy'

He had planted a seed which grew and bore fruit beyond all imagination, for from that day she knew her destiny. Already she had learnt to try her utmost to disregard pain, illness, or anything that might prevent her from taking part in whatever was going forward. Now she had determined to become a nurse and, a cripple herself to help to cure other cripples. Somehow she got herself accepted for training, and somehow in the end she succeeded in spite of recurring flares of hip disease. It was a triumph of resolution against all reason. In those days the training was very arduous with long hours and wretched living conditions. She suffered from them so much herself that she vowed "If ever I rose to be a matron no healthy girl should be the worse in health because of her work among the sick. This vow I kept with the result that when the Great War broke out in 1914 I was able to face it with a staff of young stalwart, eager girls, willing and able to give of their best."

After adventurous times as a district nurse with her friend Miss Goodford she started in her own village of Baschurch on Oct 1, 1900 what grew into the first open air orthopaedic hospital. In 1903 she consulted Robert Jones in Liverpool, and after experiencing his surgical skill herself persuaded him to see her difficult cases, and then, to her great pride and joy to act as surgeon to her primitive hospital. Thus were linked H O Thomas Robert Jones and Agnes Hunt the founders of a new school of orthopaedics and of a tradition of professional skill and personal service. The present writer was privileged to work at Baschurch and to spend many a Saturday night at her cottage nearby, an interlude between strenuous days in the wards and the theatre which was lit by her fascinating talk, which ranged the world but always returned to orthopaedics with insight and intimacy.

Miss Hunt had all the best qualities of individuality, charm, wisdom and resolution mellowed and warmed by an underlying and delightful sense of fun. She cared intensely for everything that mattered and her response to a suffering patient was immediate and exact. We would be having a most welcome meal at the end of a long day in the theatre of which she had borne the brunt then would come a call from a distant ward

*This is My Life* Agnes Hunt Blackie 1938

if she would go out into the dark with her crutches and pain showing with that half-smile the effort and victory her courage. Relief and reassurance went with her to the extent for she had mastered every detail and expedient of orthopaedic nursing, her eyes were quick to see what was wrong and her hands put it right with the sure touch and gentle strength of the craftsman.

Thus she was able to demand from her whole team the acquisition of skill and its generous expenditure in an untiring care of each individual—a devotion not to herself but to the common aim. She got all this from everyone worth their salt, the others could and did, go. The result was a hospital intensely alive and magnificently functional and a school of orthopaedic nursing with a superb tradition.

#### H B WILLOUGHBY SMITH, MB, BS, FRCS

Hugh Bernard Willoughby Smith, the eldest son of Mr E J Smith, of Bridlington, Yorkshire, and nephew of Dr F J Smith whose name will be familiar to generations of London Hospital men, died on July 11 in his surgery at Gainsborough, Lincolnshire, at the age of 69. He was educated at Pocklington School and at the old Yorkshire College, which later became the University of Leeds, and at the London Hospital, being a scholar in anatomy and biology. He graduated MB, BS, Lond and also took the MRCS, LRCP in 1902. He then served as house-surgeon at the London Hospital and at Poplar Hospital, where he obtained a grounding in ENT work. In the next three years he worked as senior medical officer at Pretoria Hospital, Transvaal, and gained considerable surgical experience. Returning to England, he took the FRCS in 1909 and shortly afterwards joined the partnership of Passmore and Lanyon in Gainsborough, both old London Hospital men, starting a career in general practice and surgery which continued to the day of his death. It was interrupted only during the first world war, when he served in the 4th Northern General Hospital at Lincoln and later in various units in France. In his first few years at Gainsborough there was no hospital, and the operations were performed on a portable table, and even on the domestic kitchen table, with the help of the district nurse and an anaesthetist armed only with open chloroform or ether. There were no fatalities, and the results were so remarkably good that Willoughby Smith had built up a considerable local reputation for himself by the time the John Coupland Hospital was opened in 1913, where all his later work was done.

In addition to his surgery and general practice Smith was for many years medical officer for the Gainsborough Rural District and an active member of the BMA, which he joined in 1907. He was president of the Midland Branch in 1921, chairman of the Lincoln Division in 1931-2, president of the Lincolnshire Branch in 1933-4, and representative in the Representative Body from 1928 to 1939. Outside his professional work his main interests were in natural history, especially botany and gardening, in both of which he was expert.

It is, however, as a man that he will be best remembered by those privileged to be admitted to his friendship. Sincere and loyal to a fault to his colleagues and patients, he hid a warm heart under an unemotional exterior, and it is typical of him that he mentioned only very recently that the proudest moment of his life was when he received a handshake from Lord Lister during a prize-giving ceremony at the London Hospital many years ago. We shall not see his like again in private practice. Dr Smith leaves a widow and one daughter, to whom our sympathies are given.—G W J

Dr ALEXANDER ROBB FORREST, medical officer of health for the county borough of Barrow-in-Furness, died on June 22 at the early age of 44. He was a native of Aberdeen and was educated at Robert Gordon's Colleges. Having qualified M.P.S. at Edinburgh in 1925, he studied medicine at Aberdeen University where he graduated MB, ChB in 1930. After graduation he held various resident posts in hospitals in London and Aberdeen. In 1933 Dr Forrest took the D.P.H. and became senior resident surgeon of Aberdeen Royal Infirmary, which post he held until the following year when he went into general practice in Peterhead, Aberdeenshire. His duties there included those of medical officer to H.M. Prison. Three years later he

gave up his practice to become assistant medical officer of health for Barrow-in-Furness, where he had clinical charge of the school medical service and children's clinics. In this particular sphere of public health work Dr Forrest was outstandingly successful, and this was in no small measure responsible for his appointment two years later as medical officer of health and school medical officer. He thus achieved the distinction of becoming head of a department without previous experience as a deputy.

During the next few years his responsibilities were heavy indeed, for in addition to the complete reorganization of the school and welfare clinics he was called upon to organize and operate the first-aid and emergency services required for civil defence. In 1944 his thesis, 'An investigation of the effect of diet and open air methods on the physical condition of children attending an open air school,' gained for him the M.D. of Aberdeen University. Although Dr Forrest had not enjoyed the best of health for some years, his devotion to duty was unflinching, and his enthusiasm gained the admiration and respect of all who came in contact with him. Shortly before his death he was appointed a member of the local hospital management committee and had accepted the interim post of acting secretary to that body. He was also an active member of the British Medical Association, and during the term 1946-7 was chairman of the Furness Division.

Dr Forrest's interests outside his profession were wide, and included membership of the Barrow Rotary Club, the St Andrew's Society, and the local branch of N.A.L.G.O. Not only was he popular among his colleagues but he enjoyed the esteem of a wide circle of friends in all walks of life. The people of Barrow have lost a zealous and respected medical officer of health who was ever ready to foster their well-being. Dr Forrest leaves a widow and a son aged 13, to whom the deepest sympathy is extended.

Dr MARTIN ALFRED COOKE who died suddenly on June 28 at the age of 76, was educated at Weymouth College and at St Bartholomew's Hospital, qualifying in 1895. He served in the Gloucester Volunteers as a private, and at the formation of the Territorial Army had attained the rank of captain. He became a major commanding a field ambulance in the London Mounted Brigade in 1908. In the 1914-18 war he commanded the Grove Hospital, Tooting, with the rank of lieutenant-colonel. For these services he was awarded the O.B.E. His first appointment on qualifying was as a house-surgeon at Stroud Hospital, which had been founded largely through the efforts of his father, Dr A. Square Cooke, whom he later joined in practice in Stroud. In 1906 he moved to Upper Norwood and entered into partnership with the late Dr William Gandy. From that time onwards one of his greatest interests was the Norwood Cottage Hospital, in the service of which he never spared himself. In his forty-two years of practice in Norwood Dr Cooke got through a vast amount of work. He was a competent surgeon and performed many operations at the hospital. He was a keen Rotarian, a past president, and an inexhaustible worker for Rotarian ideals. Dr Cooke was a man of great integrity. Many of his younger colleagues who were absent on service during the recent war have cause to remember his scrupulous care of their interests with gratitude and affection. He was beloved by his patients and respected by all who knew him. He is survived by a widow, a son and a daughter.

Dr HENRY SMITH of Kew, Melbourne, Australia, died there suddenly on June 8. He was 83, and was educated at the medical school in Newcastle-upon-Tyne and was a graduate of Durham University, where he obtained his MB in 1890 and his MD four years later. His earlier professional life was spent in the cathedral city of Durham, where he carried on a general practice combined with a surgeoncy at the Durham County Hospital. He was also part-time M.O.H. to Brandon U.D.C. Smith always endeavoured to keep in touch with the best current work and to foster the best standards of the profession. He was regular in his attendance at the meetings of the old Northumberland and Durham Medical Society and a frequent visitor at operations in the Newcastle Royal Infirmary. He was also an active member of the British Medical Association and was chairman of the Durham Division from 1922 until shortly before he migrated to Australia some twenty years ago. He settled in Kew, and there he continued to practise until his death. Henry Smith was a tall, good-looking man who was always well dressed and an outstanding figure in any company. Always very courteous and attentive, with a quiet confident manner, he was very popular with his patients, to whose interests he was devoted. He was a staunch Churchman and was a vestryman of Holy Trinity, Kew when he died. He is survived by his widow and a daughter, who is also a member of the profession.—G G T

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a quarterly meeting of the Council held on July 8 Lord Webb Johnson was re-elected President for the eighth year. Mr L E C Norbury and Mr V Zachary Cope were elected Vice presidents.

Professors and Lecturers were appointed as follows:

**Honorary Professors**—Mr Hamilton Bailey, one lecture on parotidectomy indications and technique Mr Shafik Shalhaby one lecture on amoebic liver abscess, Mr T F Cawthorne one lecture on some observations on the pathology and surgical treatment of labyrinthine vertigo of non infective origin Dr W S C Copeman one lecture on pathological anatomy of certain forms of lumbar fibrositis and the role of surgery in its treatment, Mr R W. Raven, one lecture on the properties and surgical problems of malignant melanoma Mr M W C Oldfield, one lecture on advances in harelip and cleft palate surgery following the treatment of 500 patients, Mr C H Gray one lecture on surgical treatment of the painful hip joint, Mr A C Kanwar one lecture on pulmonary telecystosis Mr J G Bonnin, one lecture on distasis of the tibio fibular syndesmosis, Mr D F E Nash, one lecture on the development of micturition control Mr W S Lewin, one lecture on acute subdural and extradural haematomata in closed head injuries, Mr Robert Roaf, one lecture on the treatment of residual disability following injuries of the peripheral nerves of the upper extremity, Mr John Loewenthal, one lecture on the treatment of intractable ulceration of the leg, with special reference to streptomycin Mr R A R T aylor, one lecture on the aetiology pathology, diagnosis, and treatment of acute pancreatitis a review of 110 cases

**Arnis and Gale Lecturers**—Mr R K Bowes, one lecture on infra red photographic studies of the superficial veins in the female and their clinical application, Mr R H Goetz, two lectures on the diagnosis and treatment of vascular diseases, with special consideration of clinical plethysmography and the surgical physiology of the autonomic nervous system

**Erasmus Wilson Demonstrators**—Mr C E Shattock, two demonstrations, Mr L W Proger, two demonstrations, Mr R M Haines, one demonstration on tumours of the ovary, Mr Guy Blackburn, one demonstration on diseases of the thyroid gland

**Arnott Demonstrators**—Mr P H Mitchiner, two demonstrations, Mr R J Last, two demonstrations, Dr F S Gorrill, two demonstrations.

The following hospitals were recognized: Sandhiffe County Hospital, Devsbury (resident surgical officer), Northampton General Hospital (resident surgical officer, surgical registrar and orthopaedic house-surgeon, Additional recognition), St Andrew's Hospital, Dollis Hill, London, N.W. (senior and junior house surgeons), Central Middlesex County Hospital, London, N.W. (the three house-surgeons), County Hospital, Whiston, Lancs (resident surgical officer, class III (rehabilitation) officer, and general house surgeon).

## FACULTY OF DENTAL SURGERY

The first election of Fellows to the Board of Faculty of Dental Surgery was held on July 16, when it was reported that Professor

H F Humphreys had been re-elected and Professors M A Rushton and H H Stones elected to the Board.

The Board welcomed members of the Orthodontic Society of Europe, who were shown the Odontological Museum by the Curator, Sir Frank Colyer, and inspected various College treasures.

The first meeting of the Faculty was held, and some 160 Fellows and Licentiates in Dental Surgery of the College attended. The President, Lord Webb-Johnson, gave a historical survey of the College and its association with dental surgery. He pointed out the great opportunity the Faculty had in promoting the art and science of dental surgery, and hoped that in the future dental surgery would look upon the College as its academic and spiritual home. The Dean then gave a short review of the various steps which led up to the forming of the Faculty and the Fellowship in Dental Surgery. The annual report of the Board, which showed that a considerable amount of work had been completed in the first year, was presented by Dr E W Fish. At the conclusion of the meeting Mr Reginald R Course was elected to represent the Licentiates in Dental Surgery of the College on the Board.

The following dental surgeons from home and overseas were admitted by the President to the Fellowship in Dental Surgery of the College: Professor Andrew Francis Jackson, Professor Sheldon Friel, Professor J C Middleton Shaw, Miss K C Smyth, Mr L Russell Marsh, and Mr B Maxwell Stephens.

The Charles Tomes Lecture was given by Andrew Francis Jackson, DDS, professor of orthodontics, Temple University, Philadelphia, on "Growth and Development from the Clinical Aspect of Orthodontics."

In the evening the first anniversary dinner of the Faculty was held in the College, and was attended by some 150 dental surgeons and guests. The toast of 'The College' was proposed by Professor Bradlaw, and the President, Lord Webb-Johnson, replied. Professor F C Wilkinson, the Vice-Dean, proposed the health of the guests, and Sir Wilson Jameson, Chief Medical Officer of the Ministry of Health, replied, and during the course of his speech referred to the important part which the Faculty would play in the future of dental surgery. The reply to the toast of the guests was also supported by Professor Jackson, who stressed the good relations which existed between this country and the United States from the academic as well as from the political point of view.

#### ROYAL COLLEGE OF PHYSICIANS OF IRELAND

T St V W Buss was admitted a Member of the College on July 9.

#### ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council of the College, held on July 24, Sir William Gillratt was re-elected President of the College. The following officers were also re-elected: *Vice Presidents* Sir William Fletcher Shaw and Mr James M Wyatt; *Honorary Treasurer* Mr Arthur A Gemmell; *Honorary Secretary* Mr Humphrey G E Arthure; *Honorary Librarian* Mr Frederick W Roques; *Honorary Curator of the Museum* Mr Aleck W Bourne.

The following were admitted to the Fellowship of the College: F R W K Allen, J B Dewar, P J Kearns, H R MacLennan, G R Sparrow.

The following were admitted to the Membership of the College: S G Aitken, I C Barne, W Barr, F Benjamin, A B Higginson.

The following candidates were elected to the Membership of the College: T M Abbas, I S R Bain, Henrietta F Banting, T L S Bynes, S Behrman, D C A Bevis, C C Bowley, T St V W Buss, L I W Cox, T E Elliot, P M Naidu, Mary E Egerton, Margaret Fitzherbert, G McI Forsyth, H D Freeth, G B Gibson, J H Gibson, A Graham, A H Grenz, Constance A Grey, H B Hattam, C C Henneberg, E Hesselberg, D W Higson, J C Holman, K R Hudson, A G Jones, J B Joyce, R A Irani, W T Kenny, G G Kerster, R A H Kmch, S Lask, T L T Lewis, Ethna W Little, E L F McConnachie, W Macfarlane, J M McKiddie, S H Madden, Helen M Mayer, G W H Millington, F L E Musgrove, C G Nairn, J R Norris, J J F O'Sullivan, J H Patterson, A C Pearson, W H Peek, S D Perchard, D Pryor-Jones, M S Qureshi, E H Rees, S McR Reid, H A Ripman, D N S Robertson, Helen M Russell, B W Sanderson, H Snyed, S A Siddiki, G A Silley, A A Smith, T Smith, G J Sophian, Christine M Stacey, P C Steptoe, C S N Swan, R A Thatcher, G S Thomas, R G Whitelaw, P de S Wijesekera, R M Williams, M S Williamson, H G Wolskel, P S Wright, R B Wright.

#### CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examination, were admitted: LRCP Ed, LRCS Ed, LRFPS Glas, on July 28: Freda M Addly, A K Bain, R G Blair, J A Brown, D Bull, E S Cohen, Ruby M Collister, Jessie McI L Duce, H Fishman, A Freedman, L I Freeman, D Giannini, P W Grant, J Hamilton, T Hannah, D P K Howie, N D Ker, A Kilpatrick, A Kwasiuk, G H Lec, W Leggat, A J Levine, Audrey E Lewer, D McN McCurrach, A W D McFntyre, Jessie K M Main, H M

Marks, Catherine R S Mitchell, Margaret E Morgan, A Muir, W W Muir, B Nash, Rosalie A H Paul, W H Reid, W J Reilly, B Seltzer, A E M Sieger, Eirlys Speck, R K Steen, D F F Stephens, J McC H Steven, J Stewart, Gwyneth Watkins, Margaret L -Watt, Sheila M Wheeler, G A Whitefield, L Wilkie Sophia W Wright.

## Medical Notes in Parliament

### NATIONAL HEALTH SERVICE

#### Younger Specialists

On July 29 Sir ERNEST GRAHAM-LITTLE reported that a large class of younger specialists including holders of grants under the various grades of the Health Scheme, had not been offered even interim contracts under the Health Service Act and were receiving approximately half the salary which they might expect from the Spens Report recommendations. He added that many of them had been qualified 10 years, were married, had families, and suffered from financial strain. Sir Ernest asked for an assurance that the adjustments would be retrospective and made quickly.

Mr BEVAN replied that no interim contracts were necessary where, as was usual, holders of junior hospital appointments immediately before July 5 were whole-time officers, because they passed as transferred officers automatically into the employment of the appropriate hospital management committee or board of governors. Any adjustment of their present remuneration (which he knew to be often less than that recommended by the Spens Committee) must await the drawing up of agreed rates with the profession, as in the case of specialists. As soon as agreed rates were evolved he would do his best to see that retrospective adjustments from July 5 were carried out quickly.

#### Attendance at Confinement

Mr PETER THORNECROFT inquired on July 29 whether under the National Health Service Regulations a mother was entitled to the presence of a doctor at her confinement if she desired it, or whether a doctor was entitled to decide that it was not necessary for him to attend in spite of the wish of the mother that he should do so.

Mr BEVAN answered that a practitioner providing maternity medical services undertook to be present at the confinement if in his opinion it was required or if summoned by the midwife in attendance. In reaching his decision he would no doubt take account of the wishes of the mother.

On the same date Mr PETER THORNECROFT further asked the Minister of Health whether under his regulations a mother could engage the services of a doctor privately and pay his fees for her confinement without losing the nursing and other benefits made available under the National Health Service Act.

Mr BEVAN indicated that this was so but wished to make it clear that the woman could not pay any fees to a doctor on whose National Health Service list she was entered.

#### Prescribing

Sir THOMAS MOORE asked on July 29 what authority had been delegated to local medical committees to prevent a medical practitioner from prescribing any drug or medicine which he considered necessary for the treatment of an insured patient.

Mr BEVAN wished it to be quite clear that patients were entitled to all drugs necessary for their proper treatment. Local medical committees had power only to investigate excessive prescribing.

On the same date Mr RANDALL asked whether Mr Bevan knew that regulations issued in connexion with the National Health Service concerning the procedure to be adopted for the investigation of excessive prescribing had created considerable feeling among the medical profession. He asked for an assurance that, while such procedure might be necessary to prevent extravagance, it would not be used to restrict the doctors.

Mr BEVAN replied that this procedure was on similar lines to that which had been in operation for many years under the old National Health Insurance Scheme. He explained that it was aimed exclusively at extravagant prescribing and would certainly not be used to restrict any prescribing necessary for the treatment of the patient.

Mr BEVAN said in reply to a question by Mr HARDY that he realized how necessary it was that all the staffs concerned should understand the provisions of the National Health Service Superannuation Scheme. Officers of his Department were available to attend meetings of employees in order to explain the scheme in detail. In response to requests from employee organizations they had already attended a number of such meetings.

## Assistants in NHS

Sir ERNEST GRAHAM-LITTLE was assured by Mr BEVAN on July 27 that executive councils had been asked to consent without question to the continued employment in the National Health Service of assistants employed before the appointed day. Mr Bevan said the remuneration of such assistants was a matter for their principals, but arrangements for grants for trained assistants without previous experience were under discussion with the profession.

## T T Milk

Mr PIRATIN asked on July 26 to what extent T T milk not bottled by the farmer was subsequently kept separate and sold as T T, and what steps Mr Strachey took to ensure that such milk was not mixed with non-T T milk.

Dr SUMMERSKILL said that in May, 1948, approximately 27% of the T T milk sold by producer-wholesalers in England and Wales was retailed as such. Under the Milk (Special Designations) Regulations T T milk sold as such must be kept separate from all other milk and sold to the consumer in sealed containers specially labelled and fitted with overlapping caps. Failure to comply with these conditions could involve dairymen in the revocation or suspension of their licences to sell T T milk. She regretted that only 27% was sold as T T milk but said that the Ministry could not govern consumer preference.

## EPIDEMIOLOGICAL NOTES

## Paratyphoid Outbreak

There has been an outbreak of paratyphoid B infection in Eastbourne. The first patients were admitted to hospital on July 25, and 35 suspected cases had been notified to the medical officer of health up to and including Aug 2. On that date the source of the infection had not been traced, but investigations were being carried out with the assistance of the Public Health Laboratory Service. Since the illnesses began about the same time, it is thought that the patients, most of whom were children, may have been infected from a common source. There is no evidence at present that ice cream was to blame.

## Discussion of Table

In England and Wales infectious diseases were more prevalent during the week, and there were increases in the notifications of measles 622, whooping-cough 341, scarlet fever 45, acute pneumonia 37, diphtheria 33, acute poliomyelitis 13, dysentery 11.

A rise in the incidence of measles occurred in every area except in the west-midland and the south-western counties where decreases in notifications of 146 and 54, respectively, were reported. The largest rises in the incidence of measles were in Yorkshire West Riding 285 and Yorkshire East Riding 124. The fluctuations in the local trends of whooping-cough were in general quite small, and the only large rises in notifications were in Lancashire 64 and Cheshire 55. The only variations of any size in the returns of scarlet fever were an increase of 25 in London and a decrease of 25 in Surrey. The chief features of the returns for diphtheria were rises in Durham 11 and Lancashire 8. In Lancashire 18 of the 42 cases in the county were notified in Liverpool C B.

An increase in the notifications of dysentery from 5 to 24 was recorded in London (Hampstead 6, Kensington 6). The only other large return for dysentery was 11 in Lancashire. Acute poliomyelitis reverted to the level of a fortnight earlier. The largest numbers of notifications were Lancashire 6 (Manchester C B 5), London 5, Essex 4 (Saffron Walden R D 2), Middlesex 3, Durham 3, Wiltshire (Swindon M B) 2, Staffordshire 2, Yorkshire West Riding 2, Glamorganshire 2.

In Scotland an increase of 20 was recorded in the notifications of acute primary pneumonia. There was a decrease in the incidence of scarlet fever 41, measles 13, and dysentery 9. In contrast to the general trend a slight increase in the notifications of scarlet fever occurred in the eastern area.

In Eire increases were recorded with returns for whooping-cough 29 and measles 20, and decreases included diarrhoea and enteritis 16 and diphtheria 5. The largest outbreaks of whooping-cough were in Kerry (Kenmare R D) 25 and Donegal (Stranorlar R D) 15.

In Northern Ireland an increase of 25 occurred in the notifications of measles in Belfast C B.

## Week Ending July 24

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,747, whooping-cough 3,359, diphtheria 139, measles 8,501, acute pneumonia 385, cerebrospinal fever 25, acute poliomyelitis 39, dysentery 108, paratyphoid 9, and typhoid 13.

No 29

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 17.

Figures of Principal Notifiable Diseases for the week, and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland. Figures of Births and Deaths and of Deaths recorded under each infectious disease, are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases, a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	25	3	13	—	2	60	1	21	2	—

Whooping-cough* Deaths	3 416	258	18	117	10	1 931	217	40	53	4
Deaths (0-1 year) Infant mortality rate (per 1 000 live births)	276	33	35	7	10	359	42	70	24	8
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	4,090	630	507	140	104	4,149	681	581	148	111
Live births Annual rate per 1 000 persons living	8 363	1340	915	351	253	9,687	1574	1097	396	275
Stillbirths Rate per 1 000 total births (including stillborn)	197	28	29	—	—	216	15	26	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county) will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales (London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

## Medical News

### Central Health Services Council

The Minister of Health, Mr Aneurin Bevan, has announced the members of the Central Health Services Council. It consists of 41 members, six *ex officio*. Of the other 35, one appointment is still to be made. The secretary is Mr. E. J. S. Clarke, of the Ministry of Health. The council held its first meeting on Tuesday, July 27, when Mr. Fred Messer, M.P., was elected chairman and Professor Henry Cohen vice chairman. The full list will be published next week.

### Mr Bevan Meets Chairmen of Executive Councils

The Minister of Health met the chairmen of the 138 executive councils on July 28 for the first time to enable him to receive first hand reports on the working of the services. The meeting also provided an opportunity for an informal exchange of views. Mr. Bevan thanked the councils for the way in which they had carried out the enormous burden of work which had fallen on them during the past few months. Reviewing the progress achieved, he said that the vast majority of doctors throughout the country were co-operating in the effort to make the new Service a success. A number of authenticated cases had, however, been brought to his notice of doctors who were discriminating in selecting patients or in the standards of amenities provided for public and private patients. He believed it was only a very small minority of doctors who were behaving in that way. He hoped that any cases which came to light would at once be investigated by the local medical committees, representing the medical profession. It was far better that the profession itself should, if possible, deal with complaints of this kind, and he felt sure that this was what the profession would wish.

### New Viennese Journal of Physiotherapy

A new journal entitled *Physikalische Therapie Bader- und Klima heilkunde* has been started in Vienna by Springer. It is intended to discuss all aspects of physiotherapy, climatology, and balneology.

### New Research Fellowships in Diabetes

The Lund Research Fellowships of the Diabetic Association have been allotted to the following:

1947-48—Dr J. A. L. Gilbert (full time) in the Department of Therapeutics, the Clinical Laboratory, Royal Infirmary, Edinburgh. "Problems in Diabetic Pregnancies." Dr J. Hildes (part time) at Hammersmith Postgraduate School. "Studies in Liver Glycogen." Dr J. A. Robertson (part time) at King's College Hospital. "Renal Complications of Diabetes."

1948-49—Miss G. Audy (part time) in the Department of Biochemistry, University College, London. "In vitro Studies of Insulin Action." Mr H. H. Fouracre Barns and Dr M. E. Morgans (part time) at the Medical Unit, University College Hospital. "Animal Experiments in Diabetic Pregnancies." Dr H. Harris (full time) at the Galton Laboratory, University College. "Diabetic Heredity."

### The British Rorschach Forum

At a recent meeting convened by Dr C. J. C. Earl the original Forum, which had been an informal group, was dissolved and reconstituted. The objects of the new Forum are to facilitate the exchange of views among those using the Rorschach test, to safeguard professional standards in the use of the Rorschach Method, and to encourage research among Rorschach workers. The Forum will consist of honorary fellows and members. Qualifications for future membership have been agreed and will include satisfying a selection committee of ability to use the test as a diagnostic method, as well as recognized qualifications in psychology or psychiatry, with clinical experience and experience in using the test professionally for not less than one year. The officers are Dr C. J. C. Earl (chairman), Miss Theodora Alcock (secretary), Dr W. Mons (treasurer). The subscription for both fellows and members is one guinea a year. Further information may be obtained from the Secretary, c/o The Tavistock Clinic, 2, Beaumont Street, London, W.1.

### Register of Orthoptists

A new Register of Orthoptists has now been published by the Board of Registration of Medical Auxiliaries, and medical practitioners can obtain a copy free on application to the registrar of the board, Tavistock House North, Tavistock Square, London, W.C.1.

### Wills

Mr Philip Edward Homer Adams, of Theberton, Leiston, Suffolk, left £52,073. Surgeon Rear-Admiral Robert Harry Mornement, late R.N., of London, W.1, left £919. Dr Percival Henderson, of Whitley Bay, Northumberland, left £9,957.

## COMING EVENTS

### Community Education for Mental Health

In connexion with the International Congress on Mental Health, which will be held at Central Hall, Westminster, London S.W., from August 11 to 21, the National Association for Mental Health (39, Queen Anne Street, London, W.1) has arranged a specialist meeting on 'Community Education for Mental Health' to be held at Westminster School Hall, Little Dean's Yard London, S.W., on Friday, August 20, at 2.30 p.m. The meeting will be presided over by Dr George S. Stevenson, medical director, National Committee for Mental Hygiene (U.S.A.), and member of the executive committee of the International Committee for Mental Hygiene. Addresses will be given by the following speakers: Dr Denis M. Odium (Vice President, National Association for Mental Health), 'The Future of Mental Health in England and Wales'; Dr H. Bersot (Secretary General European Committee for Mental Hygiene), 'Mental Health Education in Switzerland'; Miss Nina Ridenour, Ph.D. (Executive Officer, International Committee for Mental Hygiene), 'Mental Health Education through the Press and Theatre, etc.' The discussion following these addresses will be opened by Miss H. E. Howarth, M.A. (Tutor in Social Work, Institute of Psychiatry, London).

### Congress on Population

The International Congress on Population and World Resources in Relation to the Family will be held at Cheltenham on August 23-28. The Family Planning Association has organized the Congress, which will include sessions on the following topics: world resources; essential standards of living; migration as a factor in the adjustment of national populations; sociological implications of family limitation in various typical countries; birth control as a factor in the adjustment of national population; ethical and medical advantages of planned family limitation; current and future research in problems of fertility, infertility, sex, and marriage; agencies for the dissemination of knowledge and propaganda. Group sessions will also be held to discuss improvement of international liaison, education of more primitive peoples in matters of sex, the present situation in Germany, sex education, and marriage guidance. The fee for registration, which includes provision of printed *Proceedings* is £2, and applications should be addressed to the Cheltenham Congress Organizer, 37, Park Street, London, W.1.

## APPOINTMENTS

COOKE R. T. M.D. Pathologist to Harlepool's Hospitals Management Committee.

MANCHESTER UNIVERSITY—The following appointments are announced: Lecturer in Medicine H. T. Howat M.B. Ch.B. MRCP. Honorary Clinical Lecturer in Medicine H. J. Wade M.D. MRCP. Lecturer in Medical Neurology G. G. E. Smyth M.D. FRCP. Lecturer in Otolaryngology H. P. Lawton FRCS. D.L.O. L.D.S. Lecturer in Child Health A. Holzel M.D. DCH. Special Lecturer in Human Serology Fred Stratton M.D. Honorary Lecturer in Experimental and Radiation Therapeutics Harold Jackson M.Sc. M.B. Ch.B. Ph.D. Assistant Clinical Director of Chronic Rheumatism Research Centre H. S. Barber M.D. FRCP. Chief Assistant in Chronic Rheumatism Research Centre Oscar Janus M.B. Ch.B. Physician in Charge of Rheumatism Research Clinic J. S. Lawrence, M.D. M.D. MRCP. Lecturer in Clinical Prosthetics A. J. Milne Gall FRCP and L.R.C.S. Ed. Chelmsford Lecturer in Surgery for Dental Students F. H. Scotson FRCS.

MIDDLESEX HOSPITAL London W.—Assistant Physician to Department of Psychological Medicine J. A. Hobson M.D. MRCP. DPM. Assistant Obstetric and Gynaecological Surgeon I. M. Jackson FRCS. MRCOG. Anaesthetist A. J. H. Hewer M.B. B.S. D.A.

SCUNTHORPE AND DISTRICT WAR MEMORIAL HOSPITAL—Physician J. H. Derek Millar M.D. MRCP. Surgeon V. P. McAllister M.Ch. FRCS. Ed. Anaesthetist W. N. Rollison M.B. Ch.B. D.A. Assistant Ear, Nose and Throat Surgeon R. Morton FRCS. Ed. Cardiologist J. W. Brown M.D. FRCP.

## BIRTHS, MARRIAGES, AND DEATHS

### BIRTHS

Hall Smith—On July 21 1948 at Whitehaven The Drive Hove to Dr Angel Hall Smith and Dr Patrick Hall Smith a second son.

McAnallen—On June 19 1948 at St Mary's Nursing Home to Patricia (Atkinson) and Dr J. McAnallen of 53 Watcombe Circus Nottingham a daughter.

Perey—On July 23 1948 at Birmingham Maternity Hospital to Joyce (Glover) wife of Dr H. Gordon Perey M.B.E. a daughter.

Tanner—On July 24 1948 to Evelyn Winifred wife of Mr Norman Tanner FRCS a son.

### DEATHS

Castellain—On July 23 1948 after a long illness Herménégild C. Pouriaès Castellain M.D. of Moseley Birmingham.

Dickson—On July 25 1948 after a short illness while at 21 Newlands Avenue Thames Ditton Surrey William Arnott Dickson M.D. FRCS. Ed. MRCP. DPH. of Parkhill Kirkcaldy Fife.

James—On July 25 1948 at Castle Hill Fishguard Pembrokeshire, sudo Thomas Hitchens James M.R.C.S. L.R.C.P.

McIver—On July 24 1948 at his home in Bexhill Sussex Colin McIver M.D. M.R.C.S. L.R.C.P. Lieutenant-Colonel I.M.S. retired.

*Ovaltine*

A. WANDER, LTD  
5 and 7 Albert Hall Mansions,  
London, S.W. 7

M337

At no time, throughout the span of life, is the proper and orderly balance of the important food factors more readily disturbed than during the period of active growth and development

The food supply of every child should therefore contain an adequate proportion of essential nutritive elements if normal progress is to be maintained. The construction of an entirely correct dietary to suit the varying requirements of each individual is, however, beyond the possibility of realisation in ordinary practice

Many physicians ensure that the ordinary dietary of the young patient is safe and adequate by advocating the daily addition of 'Ovaltine' which is a natural food tonic prepared from milk, eggs, malt extract, cocoa and soya. The deliciousness of 'Ovaltine' makes it most acceptable to every child while it is readily assimilable even by digestions impaired with disease

## PAIN ENDS...

Pain is almost always accompanied by nervous manifestations and often, too, by fever. Hence, pain suppression is usually only a part of the therapeutic task. Pain must not only be stopped but the associated nervousness must be calmed and an existing high temperature reduced to normal.

Veganin\* is an efficient means of achieving these objectives. Because of its synergistic combination of acetylsalicylic acid, phenacetin and codeine, the effect of Veganin is rapid and prolonged. The patient experiences almost instantaneous relief from pain, the nervous irritability and fever quickly subside, preparing the way for rest and recuperation. If no fever exists, Veganin does not lower the temperature.

*Composition: Each tablet 11.8 grns contains w/w Acid Acetylal 32.68% Phenacet 32.68% Codeine 0.99% excipient ad 100.00%*

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Repair of Inguinal Hernia

**Q**—What are the relative merits of whole-skin graft and the cutis graft in the repair of inguinal hernia? What is the exact technique of each and what are their disadvantages? Are implantation dermoids and sepsis a danger in the whole-skin graft method? Is it true that the late results of fascial grafts are disappointing? If a hernia repaired with fascia has not recurred after twelve months may one conclude that as in ordinary repairs the time of greatest danger is past?

**A**—It is not possible to give a short answer to this question. The following papers should be consulted: on whole-skin graft (Mair, *Brit J Surg* 1945, 32, 381, and 1946, 34, 42), on the cutis graft (Vihlein, A, *Arch Surg* 1939, 38, 118, and Cannaday, *Amer J Surg* 1945, 57, 382). These references are sufficient to cover the greater part of surgical knowledge on this problem and on what is still regarded as an experimental method. The disadvantages which might be expected—sepsis and dermoid formation, for example—are not encountered in either the experimental preliminary animal operations or the clinical series in significant proportion. Later histological studies of buried skin grafts in man and animals rather tend to show a loss of epidermal elements. The late results of fascial repair are no more unsatisfactory than would be supposed in view of the unfavourable group of cases for which this method is employed. Most recurrences are within six to twelve months of operation (Edwards, H, *Brit J Surg*, 1943, 31, 172). This reference might be added as perhaps the one most generally useful and comprehensive on this point.

### Synthesis of Optically Active Substances

**Q**—Is it possible to synthesize an optically active product from purely non-living materials? What is the significance of the asymmetrical carbon atom in vital processes?

**A**—Yes. It is also possible to synthesize optically active substances in which the activity is due either to an asymmetric atom other than carbon (the first such example being phenyl-benzyl-allyl methyl-ammonium iodide in 1899) or to a form of molecular dissymmetry in which there is no single asymmetric atom. A survey covering a number of such cases has been given lately by F. G. Mann (*J R Soc Arts* in press). There is little evidence on the biological significance of asymmetric carbon atoms. The case of gramicidin-S lately investigated by J. I. Harris and T. S. Work (*Nature* 1948, 161, 804) is however, suggestive. Structurally, this appears to be a closed ring consisting either of five amino-acids or of the same sequence repeated before closure of the ring (Consden, Gordon, Martin, and Syngé, *Biochem J* 1947, 41, 596). Four of these amino-acids are in the *l*-configuration and the fifth is in the *d* or (so-called) unnatural configuration. It has been suggested that the presence of a *d*-configuration would promote cyclization and that it is to the latter that the antibacterial action of gramicidin-S is to be attributed. If confirmed, this would suggest further that the 'unnaturalness' is not in the *d*-configuration as such but in the possibility that a mixture of *d* and *l* forms can lead to "unwanted" structures including cyclization.

### Colour of the Tongue

**Q**—Some people have a pale pink tongue and most have a red one. Why is this? Is it of any significance?

**A**—The colour of the tongue depends on the thickness of its epithelial integument, its vascularity, and the haemoglobin content of the blood. Thus in anaemia it may appear pale pink and in polycythaemia rubra a deep purple. There is a considerable variation in normal persons in the first two properties which can account for differences in colour. Provided there is no evidence of a glossitis and there is no anaemia, differences in colour have no significance.

### Care and Treatment of Nails

**Q**—(a) What is the explanation for the presence of the half-moons at the nail bases? (b) What are the causes and treatment of recurrent hangnails? (c) What general advice should be given to women in order that they may keep their nails attractive—that is with the use of nail polish and nail polish remover, etc.—and yet healthy with special regard to brittle nails?

**A**—(a) The 'half-moons' deep to the proximal portions of nails correspond to the nail matrices, that specialized portion of epidermis from which the nails themselves grow. From this point they rest upon but are not in organic connexion with the nail-beds. (b and c) Hangnails are the result of trauma, rough usage, water maceration, or contact with irritants, particularly alkaline irritants. Biting and picking the nails, household chores and manual labour may provoke the trouble. Toilet care of the nails is important: the cuticle should be gently pressed back with a towel or orange stick after washing to prevent it being drawn along the length of the nail. Regular care in this fashion from early childhood is desirable. The application of a little emollient at night is a useful prophylactic measure. Nail polish is harmless except in rare cases of idiosyncrasy, but serves no useful purpose. Preparations used to remove nail polish are harmful and should be kept off the cuticle (nail-fold) and adjacent skin. Cuticle removers are also harmful, being alkaline, and should be used sparingly and with care. Brittleness and other dystrophies of nails are almost invariably a reflection of some disturbance of general, circulatory, nervous, or emotional health and call for general treatment.

### Arsenicals and Sulphonamides

**Q**—Is it safe to give an arsenical compound and a sulphonamide at the same time? In the bush, without laboratory facilities, one has often to treat cases (I refer more particularly to ophthalmic cases) which may be due either to gonorrhoea or to syphilis or to both and as the clinical test is wasteful of time and may be so of drugs, I should be grateful for advice if the risk is small it may be justified.

**A**—There is no reason why arsenicals and sulphonamides should not be given at the same time except that both are somewhat toxic drugs where convenient, therefore, it is just as well not to use them concurrently. The danger of giving substances containing sulphur during sulphonamide therapy has been exaggerated in the past and is little feared nowadays. When a lesion is considered to be due to syphilis or gonorrhoea or both and a definite diagnosis cannot be made, it is wise to prescribe treatment for both conditions in the interest of the patient, it is surely more economic in such circumstances to use a remedy unnecessarily than to allow the patient's possible syphilis to do irreparable damage. Penicillin, arsenic, and the sulphonamides are all comparatively cheap nowadays, and the cure of the patient is more important than the cost of remedies.

### Transplantation of Ureter into Appendix

**Q**—At a bush hospital in the Congo it was necessary to perform transplantation of the ureters on seven or eight occasions because of extensive destruction of the urethra through either disease or post-partum sloughing. On two occasions the right ureter was lying in close proximity to the appendix so it seemed natural to utilize the proximal 1/2 in (1.25 cm) for threading the ureter into the caecum, the left ureter being transplanted into the pelvic colon in the usual way. Both patients made good recoveries, and though there is no follow-up system the cases being scattered over such a large area, one patient was known to be alive and leading a useful life three years after operation. Do the more fluid contents of the caecum constitute a strong contraindication for utilizing the appendix in this way?

**A**—The lower down the colon the ureter is implanted the less likelihood is there of getting reflux infection. Any surgeon who has succeeded in implanting the ureter into the appendix without ill effects, particularly while working in the Congo, is to be congratulated, but the risks are appreciable and are not to be taken if it is possible to implant the ureter at a lower level in the colon.

### Recurrent Corneal Ulcers

**Q**—How should one treat recurrent corneal ulcers? What is the usual cause?

**A**—Recurrent corneal ulceration is generally the result of some endogenous disturbance. It may be part of the picture of phlyctenular ophthalmia, of acne rosacea keratitis, keratoconjunctivitis sicca, and many other ill-defined entities. When the recurrent ulceration is confined to one eye a local factor may be responsible such as recurrent erosion after injury, recurrent marginal ulceration in an arcus senilis, and repeated breakdown of the cornea in a degenerate eye. The first step in the management of recurrent corneal ulcer is, therefore, an accurate diagnosis, as distinct from the mere anatomical designation of recurrent corneal ulcer. Treatment will then depend on the underlying condition. The usual local treatment for corneal ulcer producing irritation of the eye is the instillation of 2 drops of 1% atropine sulphate solution two or three times a day, and the eye should be kept bandaged. The dangers of bandaging an eye if there is a mucopurulent discharge and of instilling atropine drops in the elderly must be borne in mind.

### Metallic Taste

**Q**—Many patients complain of a metallic taste in the mouth—presumably a preservative. What is it and in what food is it present?

**A**—The only obvious causes for a metallic taste in the mouth are foods treated with artificial sweetening agents such as saccharin and dulcin. Dental fillings of different metals may set up an electrolytic action in the mouth, and a metallic taste is also experienced sometimes by patients with trigeminal neuralgia. It may also form part of a neurosis, or be due to a lesion of the olfactory nerve or an irritative lesion involving the uncinate gyrus.

### Early Rheumatoid Arthritis

**Q**—Can anything be done for early rheumatoid arthritis in the metacarpophalangeal joints? A woman aged 35 complains of pain and stiffness in these joints in each hand. Both her parents have marked rheumatoid changes in their hands. There is nothing to be made out by an examination of the patient's hands but a radiograph discloses peri-articular decalcification with possibly slight loss of joint space and haziness of the margins especially in the metacarpophalangeal joints of the index fingers. Her general health is good, she has had three children, is very active and is of slight build. There is no known focus of sepsis or evidence of endocrine disturbance. Sedimentation rate has not been taken.

**A**—This seems to be a case of early rheumatoid arthritis, but before coming to a definite conclusion as a basis for treatment it would be important to have the sedimentation rate taken, and other more detailed investigations may be necessary. In these days when women, especially housewives, are using their hands to a much greater degree than was the case before the war, peri-articular fibrositis of the knuckles is not uncommon and is easily taken for true rheumatoid arthritis. It would be safe to give cod-liver oil, which seems to exert a beneficial effect in raising resistance, and guaiacal carbonate with calcium aspirin, 5 gr (0.32 g) of each three times a day. More specific measures—gold, vaccines, etc.—should not be undertaken without further investigation. Simple contrast baths for the hands would also help by stimulating the circulation, which is often poor in such cases. The prospect of arrest in this case seems to be good with proper treatment, but it is essential that this should be undertaken without delay.

### Trophic Sores in Paraplegia

**Q**—What is the best method of treating a deep sinus of the hip region in a paraplegic patient? The sinus started as a pressure sore which developed into a deep trophic ulcer.

**A**—The problem of long-standing trophic sores with sinuses of this type in paraplegic patients is a baffling one. It is always extremely difficult, and often impossible, both to avoid the development of such a sore and to make it heal. The main principles of treatment are to avoid further pressure on the

affected area so far as possible, though this is by no means always practicable, and to maintain the area in as sterile a condition as possible by frequent attention to cleanliness and by the use of suitable local applications. The particular solution employed is not always a matter of importance, and it may be advantageous to change the nature of the local application from time to time. Solutions which are often useful include aqueous penicillin and sulphonamide preparations, acriflavine in spirit (2%), and phenoxetol, a solution of which is claimed to be effective against *Pseudomonas pyocyanea*. The flat trophic ulcer is a rather different problem—it responds very well to excision and split-skin grafting.

### Visual Screening in Industry

**Q**—Of what value is the 'sterosette' or 'sterometer' in industrial visual screening methods? Can these instruments take the place of routine refraction in workers who are being selected for very fine work?

**A**—The "sterosette" was first introduced some years before the war. It was considered by a subcommittee of the Council of British Ophthalmologists, who decided not to recommend the use of the instrument except by ophthalmologists, since the interpretation of the results could be very variable. It was discovered that the findings might be either too harsh or too lax. There is no sure and certain method of "visual screening" except by a complete ophthalmic examination by an oculist. For example, a man may have perfect central vision with good muscular balance and stereopsis and yet be a danger to himself and his fellow-workers by reason of a defect in the field of vision. Such instruments are safe in the hands of an ophthalmologist but not in those of a nurse or technician.

## NOTES AND COMMENTS

**Learning to Read**—Dr W. NICCOL (Westgate Gloucester) writes: Among the many circumstances which may retard a child's progress in learning to read, your expert ("Any Questions?" July 3, p. 59) omits to mention congenital word blindness, a disability known to ophthalmologists which, though it may be rare, is probably more common than is expected. It seems important that school medical officers and educationists should be aware of it. The occurrence of word blindness as a result of cerebral disease is a long established fact. Its occurrence as a congenital anomaly has received little attention. The child with congenital word blindness is usually of normal intelligence, he may even excel in certain subjects—e.g., arithmetic—but he seems unable to recognize and to remember written (or printed) letters and words. He is like a child with no ear for music compelled to be a chorister. A vivid picture of congenital word blindness has been given by Ashdown Carr (*Trans. Oph. Soc.* 1937, 57, 579). The subject has also been dealt with by Professor Ronne (*Trans. Oph. Soc.* 1936, 56, 331), and a sufferer from congenital word blindness has described her personal experiences (*Brit. J. Oph.* 1936, 20, 73).

**Treatment of Polycythaemia**—Dr A. PINEY (London, W.) writes: The answer to the question about the treatment of polycythaemia (July 24, p. 235) is, I think, both misleading and incomplete. Thus it implies that P<sup>22</sup> is, in fact, the treatment of choice, whereas it is now known that the incidence of leukaemia in cases of polycythaemia treated in this way is higher than in those treated by other methods. Again, there is no mention of the extreme discomfort of nitrogen mustard. Finally, the admirable method of treatment by bledine and small maintenance doses of phenylhydrazine hydrochloride by mouth is ignored. This method will keep most of the patients in good health for many years, but if the slight risks of the drug are not felt to be justifiable an equally good result is obtainable by bleeding at intervals varying from case to case.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 7 1948

## "THE RIGHT PATIENT IN THE RIGHT BED"\*

### FIRST SUPPLEMENT TO THE REPORT (1947) OF THE COMMITTEE ON THE CARE AND TREATMENT OF THE ELDERLY AND INFIRM

1 The Report (1947) of the Committee on the Care and Treatment of the Elderly and Infirm recommended the establishment of a co-ordinated geriatric service for the better investigation and treatment of disease and disability in old people. It was proposed that this service should be based on geriatric departments in selected general hospitals. The main functions of these departments would be to investigate the condition of elderly patients with a view to the arrangement of suitable treatment, to co-operate with the other departments of the hospital in the treatment and rehabilitation of such patients, to assess the condition of such patients on the completion of treatment and arrange their discharge to their own homes, or to residential hostels providing domestic care or, in irremediable cases, to long-stay annexes for prolonged nursing care, to conduct research into disease in old age, and to take part in the teaching of medical students and student nurses.

#### The Hospital Bed Problem

2 The committee has again considered the problem of the elderly chronic sick in relation to the grave difficulties experienced by hospitals at the present time in meeting the demand for beds, staffed by skilled nurses, for patients suffering from acute conditions. It believes that these difficulties are not due solely to a national shortage of beds and of trained nursing staff. It considers that they could be greatly reduced by a more economical use of the skilled nursing force at present available and of the existing beds in the more highly equipped hospitals. In particular, it thinks that the adoption of its proposals for a geriatric service would go far to solve the problem by releasing both beds and nurses "wasted" at present through their use in the care of these old people who need neither active treatment nor highly skilled nursing. In short, the original recommendations of the committee, although put forward solely in the interests of the old people themselves, merit consideration also as a means of securing a much more extensive provision than is possible at present for cases in all age groups requiring the special treatment and nursing facilities available in the acute hospitals.

3 The plan recommended in the Report of the committee would relieve the shortage of hospital beds in two ways. First, the expert investigation of all elderly patients in the geriatric departments would prevent the occupation of beds by those old people who in present conditions are allowed to become bed-fast unnecessarily owing to lack of systematic arrangements for thorough diagnosis, treatment, and rehabilitation. Secondly, through the provision of sufficient long-stay annexes for irremediable cases, and residential homes or hostels for elderly people too infirm to conduct homes of their own but not in need of continuous nursing, it would be possible to make arrangements, under the control of the hospital geriatric departments, for discharge from hospital of the large numbers of infirm old people who at present, to their own disadvantage, remain indefinitely in hospital beds because more suitable and homely quarters for them cannot be found. It might almost be said that there is a more urgent need of long-stay annexes and nursing aides than of hospital beds and trained nurses.

#### Illustrative Examples

4 The importance of the redistribution of the elderly patients occupying hospital beds is illustrated by the case, reported to the

committee by one of its members, of a fully equipped general hospital where, over a period of two and a half years, eight old men not in need of active treatment had continuously occupied beds which otherwise could have been used during the same period for 360 acute surgical cases. In the experience of another member of the committee, the establishment of special annexes for elderly patients of three categories—ambulant, frail ambulant, and senile confusional—has resulted in a reduction in the average time spent by such patients in hospital wards from 260 to less than 100 days, and has thus very materially increased the capacity of the hospital to provide for acute cases. Yet another example described to the committee is that of a public assistance institution which, on being taken over for use as a general hospital, contained 714 elderly chronic sick, of whom all but 200 were bed-fast. Through the substitution of thorough diagnosis and active treatment for the comparative neglect which they had formerly endured, many of these bedridden patients were sufficiently rehabilitated to be discharged, and over a period of approximately 12 years the "turn-over" of elderly chronic sick patients has been increased to such an extent that the wards reserved for such cases now contain only 200 beds.

#### Short-Stay Hostels for Investigations

5 The committee now wishes to draw attention to certain other ways in which greater economy in the use of the beds and nursing staff of the acute hospitals might be effected. First, there is at present a wasteful use of both beds and staff in those cases in which elderly patients—indeed, patients of all ages—are accommodated in hospitals while undergoing investigation. The committee advocates the provision of special accommodation, adjoining the hospitals or at least easily accessible from them, in the form of hostels where such patients, when not requiring expert nursing, could spend the two or three days occupied by diagnostic procedures. These hostels could be staffed, for the most part, by nursing orderlies and attendants, with a minimum of skilled nursing supervision.

#### Convalescent Hospitals

6 A second way in which wastage could be reduced is through the provision of "half-way houses" in the form of convalescent hospitals to which patients could be transferred by ambulance when no longer acutely ill, although still unfit to be moved to ordinary residential accommodation or to the holiday homes commonly described as convalescent homes. The treatment of uncomplicated post-operative conditions, for example, could be completed satisfactorily in the convalescent hospital, where a considerably lower proportion of fully trained nurses would be required than is necessary in the acute hospital. It is essential that the specialist staff of the acute hospital should retain their responsibility in such cases until the conclusion of the treatment, but they might with advantage have the co-operation of a local general practitioner appointed as medical officer of the convalescent hospital. The committee thinks it important that the general practitioner acting in this capacity should be given a place also in the work of the acute hospital, in the out-patient department of which, for example, he could give invaluable assistance in the "screening" of elderly patients for admission as in-patients. Apart from its other advantages this association of the general practitioner with his colleagues in the specialist team at the acute hospital would be likely to result in harmonious personal relations which would obviate any difficulties that otherwise might tend to arise in regard to the allocation of professional responsibility for the care of the patients when convalescent.

\*Approved for publication by the Council of the British Medical Association

### The Out-Patient Geriatric Service

7 An important additional method of relieving the pressure on hospital beds is the extension of out-patient facilities for elderly patients. The committee considers that every large out-patient department should include a geriatric clinic under the care of a physician, whose colleagues on the hospital staff should be available to provide specialist opinions when necessary. The services of the dental surgeon and of the chiropodist should be provided and the advice of the hospital dietitian would often be of much benefit. Of great value also is the contribution that can be made by the almoner in assessing the home conditions of the patients.

8 The geriatric out-patient clinic should be conducted in close association with the department of physical medicine, since physiotherapy plays a vital part in the treatment and rehabilitation of elderly patients, maintaining in a relatively active condition many who otherwise would become bedridden and dependent on continuous nursing care. The facilities provided should include group exercises, in which old people benefit from the companionship of their fellows and from the stimulus of competition. An extended provision of these out-patient arrangements would not only make possible the earlier discharge from hospital of patients who otherwise would continue to occupy beds while undergoing rehabilitation, but would also prevent avoidable invalidism in cases which otherwise would remain untreated through failure to secure admission to the wards.

### Transport

9 It is important that transport should be readily available for conveyance of patients from the acute hospital to the convalescent hospital or the long-stay annexe and, when necessary, back to the acute hospital, and the out-patient arrangements outlined above are dependent on a supply of suitable vehicles for transporting elderly patients between the hospital and their homes. Usually the patients attending the out-patient department will be sitting cases, and for them the shooting brake, suitably adapted, is a convenient type of vehicle. There should be a shuttle service operating between home and hospital to bring patients in groups to the out-patient department for physiotherapy. The committee considers that it would be of advantage if the regional hospital boards maintained their own transport for these special purposes and were not wholly dependent on the ambulance services of the local authorities.

### Advisory Committees

10 The committee regards the problem of providing the necessary hospital and related services for old people as sufficiently important to warrant the appointment by the regional hospital boards of advisory committees on geriatrics. It is informed that one of the boards has already set up a committee of this kind to prepare a geriatric scheme for the region, and it commends this example to those regional boards which may not as yet have given the subject their attention.

### Administrative Liaison

11 The committee again emphasizes the need to establish, as recommended in paragraph 12 of its Report, standing liaison committees to co-ordinate the activities, in respect of the care and treatment of the elderly, of the administrative authorities concerned with different aspects of the problem. In particular, the geriatric service advocated by the committee cannot be operated successfully without the close collaboration of the regional hospital boards and the local authorities. For example, unless sufficient residential homes are provided for old people—a responsibility placed on the local authorities by the National Assistance Act—hospital beds will inevitably become "blocked" and the whole service will break down. Again, an adequate provision by the local authorities of home help, home nursing, and district nursing services is essential to prevent the occupation of hospital beds by old people who, given suitable assistance in their domestic problems, can be treated successfully in the out-patient department. In the opinion of the committee it is scarcely possible to exaggerate the importance of the closest liaison being maintained between the various bodies, public and voluntary, concerned with the problems of old age.

### Summary and Conclusion

12 The committee makes a number of recommendations supplementary to those contained in its Report, published in 1947, in which it outlined a co-ordinated service for the care and treatment of the elderly and infirm, based on hospital geriatric departments in association with long-stay annexes for irremediable cases and residential homes for old people needing domestic rather than nursing care. The committee now recommends

(1) the provision of short-stay hostels for patients undergoing investigation and not in need of expert nursing,

(2) the establishment of convalescent hospitals as "half way houses" for patients who are not sufficiently recovered to be discharged to their homes and who would remain under the supervision of the specialist staff of the acute hospital, assisted by a general practitioner co-operating in the work of the acute hospital and acting as medical officer of the convalescent hospital,

(3) the development of out-patient geriatric clinics in close association with hospital departments of physical medicine,

(4) the supply of readily available transport, preferably under the control of the regional hospital boards, for conveyance of elderly patients to and from hospital, including vehicles specially designed for the transport of sitting cases between the homes of the patients and the hospital out-patient departments.

In addition, the committee again emphasizes the importance, stressed in its earlier Report, of a close administrative liaison between the various bodies concerned with old people, and particularly between the regional hospital boards and the local authorities, and it suggests the desirability of advisory committees on geriatrics being appointed by the regional boards.

13 In the *Lancet* of October 8, 1947, there appeared a leading article entitled "Beds," which concluded with these words "We hope at least that the new regional hospital boards will recognize that there can be more than one approach to this crucial problem of beds. Provision of more hospital beds may be the obvious solution, but at a time when this is virtually impracticable we shall do well to concentrate on efficient use of those we have." The committee considers that much of the present inefficiency in the use of beds in acute hospitals is due to the necessity of retaining in these beds elderly patients, needing neither active treatment nor highly skilled nursing, for whom suitable provision is not available elsewhere. The committee believes that the adoption of the recommendations made in its Report, and those contained in the present Supplement, would not only bring great benefit to the elderly chronic sick but also, by facilitating the placing of "the right patient in the right bed," would go far to solve the problem of the wastage which is so largely responsible for the present shortage of beds and of skilled nurses for the treatment of acute conditions. With this latter consideration particularly in mind, the committee again urges the immediate adoption of all practicable measures to secure a greatly improved medical provision for the needs of old age.

### NATIONAL HEALTH SERVICE SUPERANNUATION REGULATIONS

Practitioners on executive council lists who had made provision for retirement by policies taken out with life assurance companies may, subject to certain conditions, opt out of the superannuation scheme. One of these conditions is that the policy must not be assigned to any other person. In cases where the policy has been assigned for the purpose of a loan on the purchase of a practice the Ministry has agreed to waive this condition provided the practitioner undertakes (1) to render the policy free from assignment as soon as possible, and in any case when he receives his compensation under the Act for the loss of the right to sell his practice, and (2) not to assign the policy again.

The special rights available under the NHS (Superannuation) Regulations to mental health officers are explained in a booklet "Superannuation Scheme for Those Engaged in the National Health Service—An Explanation," a copy of which has been supplied to all hospital employees transferred to the Service. Leaflet SDE supplements the information and has been issued to regional hospital boards and boards of governors of teaching hospitals for distribution where appropriate.

## NATIONAL HEALTH SERVICE

## ACCOMMODATION FOR MENTAL PATIENTS

The Minister of Health has issued the following list of hospitals and institutions for the care and treatment of those suffering from mental illness

## Newcastle upon-Tyne Regional Hospital Board Area (Region 1)

(a) *Hospitals Designated as Mental Hospitals*—Cherry Knowle Hospital, Ryhope, Sunderland (Sunderland Mental Hospital), Cumberland, Westmorland, and Carlisle Mental Hospital, Carlisle, Durham County Mental Hospital, Winterton, Sedgfield, Stockton-on-Tees, Gateshead Mental Hospital, Stannington, Newcastle upon-Tyne, St Nicholas Hospital, Gosforth, Newcastle upon-Tyne, St George's Hospital, Coldingwood, Morpeth, Northumberland, St Luke's Hospital, Cleveland, Middlesbrough

(b) *Hospitals and Institutions Directed to be used as Mental Deficiency Institutions*—Dovenby Hall Colony, Cockermouth, Cumberland, Home of Industry ("Bow Villa"), Morpeth, Northumberland, St Andrew's Colony, Northgate, Morpeth, Northumberland, Rothbury Institution (Silverton House), Rothbury, Northumberland, Monkton Hall Home for Lads, Monkton, Jarrow-on-Tyne, Durham, School Aycliffe Colony, Heighington, near Darlington, Durham, Prudhoe Hall Colony, Prudhoe-on-Tyne, Northumberland, Bishop Auckland Institution (Oaklands), Bishop Auckland, Durham, Harton Institution, 169, Harton Lane, South Shields, Durham, West Hartlepool Institution (Howbeck Colony), West Hartlepool, Durham, St Nicholas Hospital, Gosforth, Newcastle upon-Tyne, Bensham General Hospital, Gateshead

(c) *Former Public Assistance or Public Health Institutions Designated as Mental Hospitals*—Durham Institution, 37, Crossgate, Durham, Lanchester Institution, 1, Newbiggin Road, Lanchester, Newcastle General Hospital, Westgate Road, Newcastle upon-Tyne, 4, Harton Institution, 169, Harton Lane, South Shields, Durham, West Hartlepool Institution (Howbeck Hospital), West Hartlepool, Durham, Preston Hospital, North Shields, Tynemouth, Bensham General Hospital, Gateshead

(d) *Premises Designated for the Purposes of Section 20 of the Lunacy Act 1890 as Amended by the National Health Service Act 1946*—Cherry Knowle Hospital, Ryhope, Sunderland (Sunderland Mental Hospital), Cumberland, Westmorland, and Carlisle Mental Hospital, Carlisle, Gateshead Mental Hospital, Stannington, Newcastle upon-Tyne, St Luke's Hospital, Cleveland, Middlesbrough, Bishop Auckland Institution (Oaklands) Bishop Auckland, Durham, Durham Institution, 37, Crossgate, Durham, Lanchester Institution, 1, Newbiggin Road, Lanchester, Newcastle General Hospital, Westgate Road, Newcastle upon-Tyne, 4, Harton Institution, 169, Harton Lane, South Shields, Durham, West Hartlepool Institution (Howbeck Hospital), West Hartlepool, Bensham General Hospital, Gateshead, Preston Hospital, North Shields, Tynemouth

## Leeds Regional Hospital Board Area (Region 2)

(a) *Hospitals Designated as Mental Hospitals*—York City Mental Hospital, Fulford, York, Bootham Park Registered Hospital York, North Riding Mental Hospital, Clifton, York, De la Pole Hospital (Hull Mental Hospitals), De la Pole, Wetherby, East Yorks, East Riding Mental Hospital, Beverley, Yorks, West Riding of Yorks Mental Hospital, Wakefield, Yorks, West Riding of Yorks Mental Hospital, Storthes Hall, Kirkburton, Huddersfield, Yorks, West Riding of Yorks Mental Hospital, Menston, Leeds, West Riding of Yorks Mental Hospital, Scalebar Park, Burley-in-Wharfedale, Leeds

(b) *Hospitals and Institutions Directed to be used as Mental Deficiency Institutions*—Claypenney Colony, Easingwold, Yorks, Hatfield Hall, Stanley, near Wakefield, Yorks, The Mansion, Kirkburton, near Huddersfield, Yorks, Meanwood Park Colony, Meanwood, Leeds, Yorks, and ancillary premises at Crooked Acres, Spen Lane, Kirkstall, and Leeds, Mid-Yorkshire Institution, Whitley, near Knaresborough, Yorks, Oulton Hall, Oulton, near Leeds, Yorks, Rawcliffe Hall, near Goole, Yorks, Tilworth Grange, Sutton, near Hull, Yorks, with ancillary premises at 341, Anlaby Road, Hull, Winestead Colony, Winestead, Parlington, near Hull, Yorks, Brandesburton Hall, Brandesburton, Yorks, Stoneville 112, York Street, Wakefield, Holywell House, Holywell Green, Elland Yorks, Westwood Institution, Clayton Heights, Clayton, near Bradford, Yorks, and ancillary premises at Ashfield, 269, Thornton Road, Thornton, near Bradford, Yorks, York City and District Infirmary (The Grange) 75, Huntington Road, York, County Welfare Institution, 1, Reins Road, Giggleswick, Settle, Yorks, County Welfare Institution Linton Road Wetherby, Yorks, County Hospital, 19, Bridlington Road, Driffield, Yorks, County Institution, Stansfield View, Todmorden Yorks

(c) *Former Public Assistance or Public Health Institutions Designated as Mental Hospitals*—York City and District Infirmary (The Grange), 75, Huntington Road York, County Welfare Institution,

1, Reins Road, Giggleswick, Settle, Yorks, County Welfare Institution, Linton Road Wetherby, Yorks, County Institution, Stansfield View Todmorden, Yorks, St James's Hospital Beckett Street, Leeds, 9

(d) *Premises Designated for the Purposes of Section 20 of the Lunacy Act 1890 as Amended by the National Health Service Act 1946*—York City and District Infirmary (The Grange), 75, Huntington Road, York, Odsal Institution, Rooley Avenue, Rooley Lane, Bradford, Yorks, Daisy Hill Institution, Bradford, Yorks, Clayton Institution, near Bradford, Yorks, County Welfare Institution, Staincliffe, Batley, Yorks, Halifax Welfare Home, Gibbet Street, Halifax, Yorks, St Luke's Hospital, Crosland Moor, Huddersfield, Yorks, Beverley Road Hospital, Hull, Yorks, St James's Hospital, Beckett Street, Leeds 9, County Welfare Institution, Park Lodge Lane, Wakefield, Anlaby Road Institution, 188, Anlaby Road, Hull

## Sheffield Regional Hospital Board Area (Region 3)

(a) *Hospitals Designated as Mental Hospitals*—Mickleover County Hospital (Derby County Mental Hospital), Mickleover, Derby, Kingsway Hospital, Rowditch, Derby, West Riding of Yorks Mental Hospital, Wadsley, Sheffield, 6, Carlton Hayes Hospital, Narborough, Leicester, The Towers Hospital, Humberstone, Leicester, Bracebridge Heath Hospital, Bracebridge, Lincoln, Rauceby Mental Hospital, Rauceby, Sleaford, Lincs, Notts County Mental Hospital, Radcliffe-on-Trent, Notts, Mapperley Hospital, Mapperley Hill, Nottingham, The Lawn, Lincoln, The Coppice, Nottingham

(b) *Hospitals and Institutions Directed to be used as Mental Deficiency Institutions*—Aston Hall, Aston on-Trent, Derbyshire, Makeney House, Milford, near Derby, Whittoning Hall, Chesterfield, Derbyshire, Leicester Frith Institution, Groby Road, Leicester, Stretton Hall, Oadby, Leicester, Harmston Hall Colony, Harmston, Lincoln, and ancillary premises at Bourne Institution, St Peters Road, Bourne, Caistor Institution, Kelsey Road, Caistor, Holbeach Institution, Fleet Road, Holbeach, and Cross o' Cliffe Court, Bracebridge Heath, Westdale Institution, Digby Avenue, Carlton, Nottingham, Hollow Meadows, Malin Bridge, near Sheffield, St Catherine's Institution, Tickhill Road, Doncaster, Girls' Hostel, 71-73, Scott Road, Sheffield, 4, Wales Court Institution, Kiveton, near Sheffield, Aston Hall, Aston, near Sheffield, Derby Institution (Boundary House), Uttoxeter Road, Derby, Mountsorrel Institution, near Loughborough, Leicester, Basford Institution, 121, Highbury Road, Bulwell Nottingham, Oakham Institution (The Ashes), Ashwell Road, Oakham Rutland, Sheffield Institution (Fir Vale House), Herries Road, Pitsmoor, Sheffield, County Institution, Grenoside, Sheffield, Doncaster Institution (Springwell House), Balby, Doncaster, Mansfield Institution 105 Stockwell Gate, Mansfield, Notts, Grimsby Institution, 110a, Scartho Road, Grimsby, The Gables Institution, Hundleby, Spilsby, Lincs, Newark Institution, Bowbridge Road, Newark, Notts

(c) *Former Public Assistance or Public Health Institutions Designated as Mental Hospitals*—Vale Brook Lodge Institution, Nottingham, Basford Institution, 121 Highbury Road, Bulwell Nottingham, Newark Institution, Bowbridge Road Newark, Notts, Mansfield Institution, 105, Stockwell Gate, Mansfield, Notts, Derby Institution (Boundary House), Uttoxeter Road, Derby, Babington House Derby Road, Belper, Derbyshire, Newbold Road Institution, Chesterfield, Sheffield Institution (Fir Vale House), Herries Road, Pitsmoor, Sheffield, County Institution, Grenoside, Sheffield, Springwell House, Balby, Doncaster, Bosworth Park Infirmary, Bosworth Park, Leicester, Melton Mowbray Institution, Thorpe Road, Melton Mowbray, Leicester, Mountsorrel Institution, Loughborough, Leicester, Oakham Institution, Ashwell Road Oakham, Rutland, Burton Road Institution, Lincoln, The Gables Institution, Hundleby, Spilsby, Lincs, Skirbeck Road Institution, Skirbeck Road, Boston, Lincs, Wyberton West Institution, Holland, Lincs, Holbeach Institution, Fleet Road, Holbeach, Lincs, Municipal General Hospital, Moorgate, Rotherham, Grimsby Institution, 110a, Scartho Road, Grimsby

(d) *Premises Designated for the Purposes of Section 20 of the Lunacy Act 1890 as Amended by the National Health Service Act 1946*—Vale Brook Lodge Institution, Nottingham, Basford Institution, 121, Highbury Road, Bulwell, Nottingham, Newark Institution, Bowbridge Road, Newark, Notts, Mansfield Institution 105, Stockwell Gate, Mansfield, Notts, Derby Institution (Boundary House), Uttoxeter Road, Derby, Babington House Derby Road, Belper, Derbyshire, Newbold Road Institution, Chesterfield, Sheffield Institution (Fir Vale House), Herries Road, Pitsmoor, Sheffield, County Institution, Grenoside, Sheffield, Springwell House, Balby, Doncaster, Bosworth Park Infirmary, Bosworth Park, Leicester, Melton Mowbray Institution, Thorpe Road Melton Mowbray, Leicester, Mountsorrel Institution, Loughborough, Leicester, Oakham Institution, Ashwell Road, Oakham, Rutland, Burton Road Institution, Lincoln, The Gables Institution, Hundleby, Spilsby, Lincolnshire, Skirbeck Road Institution, Skirbeck Road, Boston, Lincs, Wyberton West Institution, Holland, Lincs, Holbeach Institution, Fleet Road, Holbeach, Lincs, Municipal General Hospital, Moorgate, Rotherham, Grimsby Institution, 110a, Scartho Road, Grimsby, Mickleover,

County Hospital (Derby County Mental Hospital), Mickleover, Derby, Kingsway Hospital, Rowditch, Derby, West Riding of Yorkshire Mental Hospital, Wadsley, Sheffield, 6, Carlton Hayes Hospital, Narborough, Leicester, The Town Hospital, Humberstone, Leicester, Bracebridge Heath Hospital, Bracebridge Heath, Lincoln, Raucby Mental Hospital, Raucby, Sleaford Lincs, Notts County, Mental Hospital, Radcliffe on Trent, Notts Mapperley Hospital, Mapperley Hill, Nottingham, The Lawn, Lincoln, The Coppice, Nottingham

#### East Anglian (Cambridge) Regional Hospital Board Area (Region 4)

(a) *Hospitals Designated as Mental Hospitals*—St Andrew's Hospital, Thorpe, Norwich, Norwich City Mental Hospital, Hellesdon, Norwich, Bethel Hospital, Norwich, St Audry's Hospital, Melton, Woodbridge, Suffolk, Ipswich Mental Hospital, Ipswich, Suffolk, Cambridge Mental Hospital, Fulbourn, Cambridge

(b) *Hospitals and Institutions Directed to be used as Mental Deficiency Institutions*—Eaton Grange, Unthank Road, Norwich, Norfolk, Little Plumstead Hall, Little Plumstead, near Norwich, Norfolk, and ancillary premises at Heckingham Institution, Heckingham, Norfolk, Ely Institution (Tower House), Cambridge Road, Ely, St James's Hospital, Radwinter Road, Saffron Walden, Essex, Risbridge Institution, Kedington, Haverhill, Suffolk, Chesterton Institution, 29, Union Lane, Cambridge, Aylsham Institution, St Michael's Hospital, Aylsham, Norfolk, St Mary's Hospital (Bury St Edmunds Institution) Bury St Edmunds, Suffolk, Social Welfare Institution, Caister Road, Great Yarmouth, Norfolk, Eye Institution, Hartismere, Eye, East Suffolk, Lothingland House (Oulton Institution), Oulton, East Suffolk, Halesworth Institution (Red House), Halesworth, East Suffolk, King's Lynn Institution, St James', Exton's Road, King's Lynn, Norfolk, Tattingstone Institution (St Mary's Hospital), Tattingstone, Ipswich, Stowmarket Institution, Stow Lodge, Onehouse, Stowmarket, Suffolk, Swainsthorpe Institution, The Vale, Swainsthorpe, Norwich, Sudbury Institution, Walnut Tree House, Sudbury, Suffolk, Wicklewood Institution (Hill House Hospital), Wicklewood, Norfolk, Attleborough Institution (Wayland Hospital), Attleborough, Norfolk, Wisbech Institution, Lynn Road, Wisbech, Cambridgeshire; Woodlands Hospital, Bowthorpe Road, Norwich, Norfolk

(c) *Former Public Assistance or Public Health Institutions Designated as Mental Hospitals*—Aylsham Institution, St Michael's Hospital, Aylsham, Norfolk, St Mary's Hospital (Bury St Edmunds Institution), Bury St Edmunds, Suffolk, Sudbury Institution, Walnut Tree House, Sudbury, Suffolk, Risbridge Institution, Kedington, Haverhill, Suffolk, Social Welfare Institution, Caister Road, Great Yarmouth, Lothingland House (Oulton Institution), Oulton, East Suffolk, Swainsthorpe Institution, The Vale, Swainsthorpe, Norwich, Wicklewood Institution (Hill House Hospital), Wicklewood, Norfolk, Attleborough Institution (Wayland Hospital), Attleborough, Norfolk, Woodlands Hospital, Bowthorpe Road, Norwich, Eye Institution, Hartismere, Eye, East Suffolk, Halesworth Institution (Red House), Halesworth, East Suffolk, Tattingstone Institution (St Mary's Hospital), Tattingstone, Ipswich, Stowmarket Institution, Stow Lodge, Onehouse, Stowmarket, Suffolk, King's Lynn Institution, St James', Exton's Road, King's Lynn, Norfolk, St James's Hospital, Radwinter Road, Saffron Walden, Essex, Ely Institution (Tower House), Cambridge Road, Ely, Wisbech Institution, Lynn Road, Wisbech, Cambridgeshire

### BRITISH PHARMACOPOEIA APPROVED NAMES OF DRUGS

The General Medical Council has issued the following statement and list of Approved Names

New names of drugs have been made official by their use as the titles of monographs in the *British Pharmacopoeia*. Names for certain other drugs, for which no official monographs are provided, have been published as Approved Names, the intention being that if any of the drugs is eventually described in the *British Pharmacopoeia* the Approved Name shall become its official title. The recognition of an Approved Name does not imply that the substance will necessarily be included in the *Pharmacopoeia*. These names are now brought together for reference together with other names under which the drugs have been known. For some drugs numerous other names have been introduced, the lists that follow include, in most instances under Other Names, only the names under which the substances were originally introduced, some of these names are registered trade marks.

Since the intention is to give recognition to non-proprietary names which may be used freely by manufacturers and thus to avoid the difficulties which arise from the multiplication of names for the same substance, it is hoped that the Approved Names will be generally adopted and used in prescribing. The introduction of new names for substances for which Pharmacopoeial names or Approved Names are available is especially deprecated but if a manufacturer should desire to issue under a proprietary name a drug for which an Approved Name has been provided it is strongly recommended that the label shall bear the Approved Name of the substance in letters no less conspicuous than those in which the proprietary name is printed or written.

TABLE I—Names made Official by means of Addenda to the *British Pharmacopoeia* 1932, and by means of the *British Pharmacopoeia* 1948

Pharmacopoeial Names	Other Names
Acetarsol	Stovarsol
Acetaminophthone	Kaplon Oral Prokavon
Amethocaine Hydrochloride	Decicaine
Aniline Hydrochloride	Aceramine Yellow
Amphetamine	Benzedrine
Amphetamine Sulphate	Benzedrine Sulphate
Bromethol	Avertin
Butacaine Sulphate	Butyn
Butyl Aminobenzoate	Butesin
Carbachol	Dorol

TABLE I—cont

Pharmacopoeial Names	Other Names
Chinofon	Yatren
Cinchocaine Hydrochloride	Nupercaine
Deoxycortone Acetate	D O C A
Diodone, Injection of	Pertobridil
Diphenan	Butolan
Dithranol	Cignolin
Emulsifying Wax	Lincette Wax SX
Ergotamine Tartrate	Femergin
Hexobarbitone	Evipan
Hexobarbitone Sodium	Evipan Sodium
Hydrous Ointment	Eucerin (Hydrous)
Iodized Oil	Lipiodol
Iodoxyl	Uroselectan-B
Leptazol	Cardiazol
Menaphthone	Kaplon
Mepacrine Hydrochloride	Atabrin Quinaerine Hydrochloride USP XIII
Mepacrine Methanesulphonate	Atabrin Musonate
Mersalyl, Injection of	Salyrgan
Methylphenobarbitone (Phemitone)	Prominal
Neostigmine Bromide	Prostigmin
Neostigmine Methylsulphate	Prostigmin
Nikethamide	Coramine
Oxytocin, Injection of	Pitocin
Pamaquin	Plasmoquine
Pentobarbitone Sodium	Nembutal
Pethidine Hydrochloride	Dolantin, Demerol
Phenytol Sodium	Epanutin
Progesterone, Injection of	Proluton
Silver Protein	Protargol
Sodium Aurothiomalate	Myocrisin

Sulphacetamide Sodium	Albucid Soluble
Sulphanilamide	Prontosil Album
*Sulphapyridine	Dagenan, M & B 693
Suramin	Germanin, Bayer 205, Antry pol
Theophylline with Ethylenediamine	Euphyllin, Cardophyllin
Thiopentone Sodium	Pentothal Sodium
Vasopressin, Injection of	Pitressin
Vinyl Ether	Vinethene
Wool Alcohols	Hartolan Wax
Wool Alcohols Ointment of	Eucerin (Anhydrous)

\*Official in the Seventh Addendum to the *British Pharmacopoeia* 1932 but not included in the *British Pharmacopoeia* 1948

TABLE II—Approved Names

Approved Names	Other Names
Cetrimide	Cetyltrimethylammonium bromide, Cetavlon
Cyclobarbitone	5- $\Delta^1$ -Cyclohexenyl-5 ethylbarbituric acid, Phandorm
Dimercaprol	2,3-dimercaptopropanol, British Antilewisite, B A L
Dimethylstilbamidine	4,4'-Diamidino $\alpha$ - $\beta$ dimethylstilbene
Hexazole	4-Cyclohexenyl-3-ethyl-1,2,4-triazole, Azoman Triazole
Maphenide	p-Aminomethylbenzenesulphonamide, Marfanil
Meprochol	Trimethylmethoxypropenylammonium bromide, Esmodil is a 0.3% isotonic solution
Mesulphen	2,6-Dimethylthianthrene, Dimethyldiphenylene disulphide, Mitrgal
Pentamidine	$\omega$ -(4,4'-Diamidinophenoxy) pentane
Phenodol	Phenyl $\beta$ (4-hydroxy-3,5-diiodophenyl)-propionic acid, Bihselctan
Pholedrine	$\beta$ -Methylamino-4-hydroxypropylbenzene, Ventol
Proguanil	N-p Chlorophenyl N-isopropylbiguanide, Paludrine
Propamidine	$\omega$ -(4,4'-Diamidinophenoxy) propane
Sodium Stibogluconate	Sodium antimonyl gluconate, Pentostam
Sulbamidine	4,4'-Diamidinostilbene
Sulphadimidine	2 (p-Aminobenzenesulphonamide), 4,6-dimethylpyrimidine, Sulphamezathine, Sulphadimethylpyrimidine
Thialbarbitone	5- $\Delta^1$ -Cyclohexenyl-5-allyl-2-thiobarbituric acid, Kemthal
Thiomersalate	Sodium ethylmercurithiosalicylate, Merthiolate

#### Whitley Councils Nurses and Midwives

An emergency meeting of the Nurses' and Midwives Functional Council will be held on Aug 20 to consider the salaries of student nurses

## NATIONAL (WAR) FORMULARY

THIRD EDITION, 1947 AMENDMENT NO 2 (1948)

The following amendments to the Formulary take place on Aug 1.

## Page 19

Auristillae Hydrogeni Peroxidi			
Amend formula to read			
Solution of Hydrogen Peroxide (20 Vol)	60 min	25	Approximate Percentage
Water	to 1/2 fl oz	to 100

## Planning of New Dermatological Departments

SIR—The nature of the clinical material presenting itself at a dermatological clinic varies enormously from one part of the country to another. But the worst feature of the plan illustrated in the *Supplement* of July 17 (p 43) is undoubtedly the lack of any provision for patients to undress for examination. Most patients take a much longer time to undress than is required for their examination, and not only do they like a little privacy for it but the doctor can be better employed than in waiting for them. Each consulting-room should therefore have not less than three undressing-rooms in which the patients can don some sort of dressing-gown in privacy before they emerge in turn for examination by the doctor. Patients cannot even be "screened" without examining them.

The photographic studio has an effective length of 13 ft. A full-length portrait could not easily be secured in this space without a special wide angle lens. The Kodak clinical camera requires 24 ft including space for manœuvring. The department clerk will hardly have room for all the documents yielded by 200 patients on a 6-ft desk, even if her room is not used as a passage—I am, etc.,

Manchester

J H TWISTON DAVIES

## Rural Practice

SIR—As a rural practitioner in an extremely remote area 20 miles from a hospital I wish to endorse the many letters that have been written about our difficulties. I feel that they must be considered under the following headings.

**Capitation Fee**—In these vastly scattered areas the time-distance factor makes it impossible to look after the requisite 4,000 patients. In fact, I find that the care of 3,000 is beyond the capacity of a single man in this area, involving a daily mileage of from 60 to 100 miles and the probability of having to walk at least 5 miles to remote farms. It is impossible, therefore, to look after the number required by the State in order to qualify for (a) the maximum salary, and (b), what is more important, for a reasonable pension, which appears to be based on the number of patients on the capitation list on retirement. This precludes the possibility of a country doctor achieving the maximum pay rates, although in many cases, especially in bad weather, his work is arduous to a degree that no town doctor has ever experienced. I have yet to hear of a town doctor who has to use horses or caterpillar tractors to get to cases in deep snow, though this is our common lot in winter, not to mention the endless miles we trudge up to the knees in mud and snow. We are, as a class, isolated in every sense of the word. It is impossible to obtain specialist help, and no medical service yet devised can provide it for us. Often we are forced into performing surgical procedures with portable equipment—that is, equipment that can be carried by hand—

in cottages by oil lamp light etc., yet, despite all this extra work, worry, and physical strain, the country doctor is regarded financially as an inferior being.

**Mileage Rates**—So far, these have not been defined. It should be borne in mind that those of us who average 40,000–50,000 miles a year must use large fast cars. Small cars simply come to pieces, the average life of the average English 8 h.p. car being under six months in these rural conditions.

**Drugs**—For the drugs we dispense we get a comparatively low dispensing rate, yet we have to carry vast stocks of materials. My own stock value is usually £250 to £300. I presume that no attempt to carry this capital responsibility will be taken by the State unless this point is adequately aired.

**Telephones**—Another factor which causes us great trouble in the country is the large telephone accounts for which we are responsible. There are virtually no 2d calls in this area (because of distance), and the average cost of a call to the hospital is 1s 9d, because it is seldom that one can get the house-surgeon under 10 minutes, at 7d for three minutes. Many appointments also have to be made by telephone. An ambulance call is 4d. My telephone bill is £65 per year.

**Night Duty**—As country doctors we cannot possibly divide our work to the same extent as town doctors should be able to do in the future. It will therefore be our lot to continue to do a full duty of night work, and from the point of view of humanity it is impossible to refuse to do night duty in these areas. It is quite understandable that people in remote isolated farms and cottages get frightened in the night, and, although in many cases our night work involves reassurance only, I cannot see how assistance can be devised by which these points can be avoided.

**Midwifery**—Much song and dance is being made about mobile specialist services, especially for midwifery. The systems I have been able to examine are Gilbertian, they are classical, preconceived notions of the townsman's idea of country life, envisaging well sign-posted roads, farms with little names carefully nailed on the gates, and cottages in well lighted highways and by-ways. Also the idea of carrying a mobile hospital to some of these remote dwellings has its humorous side. And yet these people, whom we as a body serve, produce enough food for well over half the population of these islands.

There is little question that the medical services will remain much as they are. These practices have been hammered out in the process of hundreds of years by an excellent system of trial and error, and therefore they cannot, and will not, be changed by an Act of Parliament—I am, etc.,

Ruskington Lincs

T SMALLHORN

\*. The Secretary of the B.M.A. states: The pension of a general practitioner will be based on a percentage of his remuneration over all his years of service (as distinct from the remuneration at the date of retirement).

### The Public Not Informed

SIR—Thank you for publishing my letter under the above heading in the *Supplement* of July 17 (p. 49) and for appending the Secretary's reply. Doctors are probably more used to working 'flat out' than any other community, so I am glad to hear that the staff they employ at Headquarters is doing the same thing. However, I had not implied in my letter that they were not working hard, but that they discriminated between which of the profession's wishes should be carried out with dispatch and which should be allowed to drift. I cannot say that I am reassured either by Dr Charles Hull's remarks or by those in the letter of Dr Walter Woolley (p. 50).

The last plebiscite did not show the prescribed figures for further active resistance, but 64% of those voting did not approve of the Act. These thousands of doctors were virtually forced to accept service, but they were assured through recommendation C that their case was going to be put "adequately" before the public. To them the word "adequately" covered 'with the necessary speed'—i.e. before July 5. I can well believe the physical difficulties of which Dr Hill speaks, that are involved in the production of a large quantity of leaflet material. It is all the more extraordinary, therefore, that the leaflet 'The National Health Service and You' did not go to the printers till June 17. Council passed recommendation C' early in May. It was a thousand to one that the R.B. would sanction it (with only minor alterations if any) on May 28. Surely it could not have needed much intelligent anticipation to have had the leaflet passed and the printing put in hand in the middle of May so as to be able to send it out as soon as

possible after the S.R.M. It is just conceivable—only just—that it would have been a wasted effort, but things took their expected course and as nothing was done the whole of the precious weeks of June were wasted.

Just the same lack of anticipation was shown over the Minister's speech about the sign on muddle. Dr Hill proudly states that a rejoinder was issued to the Press within two hours. This was two weeks too late. If the public had been properly saturated with the facts during June, the Minister could not have made such remarks without appearing ridiculous—so much so that even he might not have made them.

There are many who hope that in the future the hard work of the secretariat will be productive of more obvious results and that the Public Relations Department will not be content with providing a "supply of background information for the Press." Nearly every day the profession is blamed in some way for things over which it has no control. This tendency will increase until our propaganda takes its proper place, which is the foreground—I am, etc.,

London N.W.1

R. HALE-WHITE

### Reflections on Superannuation

SIR—I have read with great interest the article on the above subject by Mr. A. N. Dixon of the Medical Insurance Agency (*Supplement* July 3, p. 23) and offer for the consideration of your members the following comments.

(a) Surely the scheme is more beneficial to widows than any existing scheme. There is no reduction of the pension while the pensioner lives and, subject to certain provisions, if he dies before his wife his widow gets a pension of one-third of his retiring pension. We must bear in mind that every superannuation scheme must satisfy the actuaries that the receipts and outgoings will balance.

(b) There is another point not mentioned by him of interest and that is that under the present proposals the general practitioner is treated more favourably than local government medical officers to the extent of  $\frac{1}{4}\%$  per annum.

(c) Provision for sickness. Surely once the regional boards get to work and have time to tackle the major issues first then provision for sickness and accident occurring among general practitioners working within the Service must come high on the list for priority of attention, also for their holidays—I am, etc.,

Worthing Sussex

HAROLD LEFSON

### BIBLIOGRAPHY

Leeson H. (1945) *Your Doctor of the Future*. Freer and Hayter. High Wycombe.  
— (1947) *Lancet* 1, 380.

\*. The Secretary of the B.M.A. states: There is an apparent difference, but not a real difference, between the  $1\frac{1}{2}\%$  of each year's general practitioner remuneration and the 1/80 (or  $1\frac{1}{4}\%$ ) applicable to local government medical officers. In the first place, the local government M.O. receives in respect of each year of contributing service 1/80 of his average remuneration for the last three years' service. The general practitioner receives the aggregate of  $1\frac{1}{2}\%$  of his net remuneration for each year of contributing service. While normally the salaried officer attains his maximum income at the end of his career, the remuneration curve of the general practitioner is of a different order, rising through early years to a fairly stable amount after which time it falls away considerably. It is claimed that the  $1\frac{1}{2}\%$  proposal spread over the whole period of service would have the effect of securing for the general practitioner a pension equivalent to half his peak remuneration. This would correspond with the local government medical officers' pension assessed on the average remuneration for the last three years of service, which are invariably the years when his remuneration is at its highest.

### A Protest

SIR—As a profession we have recently been exposed to threats and menaces, cajolment, more threats, more cajolment and finally a message of encouragement now that the Health Service has started and many of us are in it. The Association has promised to do its best to make the scheme a success even though financial blackmail was used to coerce many into coming in. It is therefore with peculiar revulsion that I read of a speech in Manchester in which the Minister

of Health states that he considers Tories to be worse than vermin. Many of us happen to be Tories and consider our beliefs to be as honestly and fairly held as those of other men who oppose them.

If the Minister is right, then by inference a good half of the doctors now entering the Service are men of a low moral type, somewhat akin to spivs, to use his own words. If this is so, then in the public interest every entrant should be interrogated as to his political opinions. Those who admit, perhaps under pressure, that they are Tories should then be excluded. It should be possible to do this fairly quickly and they could then take the advice given to Mr Bevan in his youth and to some of us more recently they could emigrate. It would then be interesting to see what kind of health service we possessed, and the courtesy and wisdom of Ministerial pronouncements could be assessed. It is surely most deplorable that these provocative and vulgar terms should be used by the chief of what, we may hope, may be one day a great service—I am, etc.,

Barnet Herts

G C PETHER

### Mr Bevan and the Tories

SIR—I am sure I am one of many doctors who feel outraged by the recent remarks of the Minister of Health in his reference to members of the Tory Party. Many of us without strong political convictions feel that having accepted the National Health Service it is our duty to the nation to work for its success, but how can we cultivate that essential spirit of co-operation when the Minister of Health castigates in such vile terms the majority of the doctors and a large proportion of the citizens of the land? It is rather a sad reflection on the medical profession that we have reached a compromise with a man holding such views, and I think it is necessary for the British Medical Association to make some public sign of its disapproval of such unprecedented behaviour by a responsible Minister of the Crown.

I hope this letter together with many others will help you to take some definite action in the immediate future, and perhaps if you think fit you will also find space for its publication as representative of the feelings of many doctors—I am, etc.,

Anstey Leics

K F C BROWN

### Remuneration of General Practitioners

SIR—In your annotation of July 17 (p 143) reference is made to the letter from me which you kindly published in the *Journal* of July 10 (p 110) concerning the remuneration of general practitioners. The annotation states that my estimate of a 50% loss is based on a capitation fee of about 15s. This is not quite accurate, as I quoted figures for a fee of either 15s or 18s. We seem to agree that the higher figure may be taken to represent estimated gross receipts from capitation fees plus mileage allowance, the latter being presumably applicable only to patients residing two miles or more from the surgery.

A fee of 18s for the whole of a 10,000 population represents £9,000 per annum and one of 17s 5d produces £8,713. The actual receipts in the area mentioned would probably be between these figures, since no mileage allowance would be payable in respect of some two-thirds of the population. The total receipts for an 18s capitation fee are actually less than the combined private and panel fees (excluding appointments and vaccinations) earned in the last complete year by only half the doctors in that area, so my estimate of a 50% loss is not far wrong.

One can appreciate your reference to payments in addition to capitation fees, but against this must be set the loss of income due to the termination of contracts as district medical officers and public vaccinators, together with fees for vaccinations actually performed, which account for some of the income of a great many rural practitioners. It is doubtful if the capitations for former "parish" patients will equal these sums in many cases.

Last week we were asked to inform the local executive council if we wished to accept the basic payment of £300 per annum. I wrote to the clerk to inquire if he would state what capitation fee would be payable with or without this salary. In his reply he said that he did not know the actual amount of the capitation fee, the amount of mileage allowance or the payment to be made in respect of drugs supplied by practitioners. The clerk

realized "that this is a deplorable state of affairs," and said he has had several similar inquiries, "to all of which I have had to confess my complete ignorance." One naturally assumes that the *B M J* has good grounds for the figures quoted in the annotation, but it is amazing that the local executive council should have received no such information from the Ministry to pass on officially to the doctors in its area.

This week's *Radio Times* contains an official advertisement of the Ministry of Health which points out that under the Health Service no fees are payable by patients to their family doctor, who is now "properly paid out of public funds to which all contribute as taxpayers." Is it not true that the Minister and his supporters were given proof that, with the fees hitherto published, a great many doctors are *not* "properly paid"? In the past there seems to have been too much concentration on various principles, particularly the retention of goodwill, with which a Socialist cannot be expected to have much sympathy. If greater attention had been given to the question of remuneration the Minister might have been more understanding and we might have secured better terms. As things are, politicians are liable to ask why this matter was not raised and discussed sooner.

Unless considerable changes are made it seems certain that in the future it will be difficult to get men to go into practice in country districts. Such diminished numbers as may still take up medicine may well feel that the only way to earn a satisfactory professional income will be to go into crowded districts where it is possible to hold lists of three or four thousand patients, but where the numbers will be such as to make careful and adequate treatment impossible. The Health Service and the patients must then inevitably suffer, and the standard of medicine, so far as the general practitioner is concerned, must fall—I am, etc.,

RALPH GREEN

### Post Office Medical Officers and NHS

SIR—Dr Clifford T Roberts (*Journal* July 17, p 177) appears to be under some misapprehension about free choice of doctor by Post Office personnel. Although they were on the lists of P O M O s they could if they wished call in their private doctor when sick at home or they could become voluntary subscribers under the NHI and choose a panel doctor. The P O M O countersigned the certificates, and if the patient was off sick over a certain time he was asked to attend the P O M O's surgery if fit to travel for examination. If the patient was unfit to travel, a local P O M O was requested to visit him, but he still remained under his private or panel doctor. If he elected to be attended by the P O M O and lived outside the area of his own P O M O the local P O M O attended him and issued pink certificates, being remunerated at special rates per visit.

I have never, as P O M O had any unpleasantness with the private or panel doctors of the P O employees on my list. The system has worked well and might be compared to that of the R M O s under the NHI. We P O M O s do indeed feel a sense of great injustice in being deprived of our appointment with loss of income and capital—that, too, at a few weeks' notice of an appointment which we understood was secure until the age of 65 years.

I understand that police surgeons feel as we do, and I believe a majority of members of the force would prefer to remain on the old basis with the police surgeon as their medical attendant. Surely the question could and should be dealt with in the amending Act—I am, etc.,

London NW 1

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton-le Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley

## RECENT ADVANCES IN OUR KNOWLEDGE OF THE Rh FACTOR\*

BY

**D F CAPPELL, MD, FRSED**

*Professor of Pathology University of Glasgow*

It seems appropriate to begin with a general survey of the problems which knowledge of the Rh factor has helped to clarify. As usual in scientific work, the problems become more complex as further insight is obtained, but without doubt the present state of knowledge is an immense advance over the conditions prevailing ten years ago, when Darrow (1938) so fully reviewed what was then known about the aetiology of haemolytic disease of the newborn. First, I should like to say that the term "Rh factor" as originally used seems unsuitable for the designation of all the antigens now known to exist in association with it in man, and I think it better, to use the term "Rh blood group" to cover this field. The term "Rh factor" might then be used to distinguish the original component common to man and the rhesus monkey. It seems rather inappropriate to designate as Rh factors red cell antigens which have not been demonstrated in the cells of rhesus monkeys.

### Discovery of the Rh Blood Group and its Clinical Significance

We owe our fundamental knowledge of the original Rh factor to the brilliant work of Landsteiner and Wiener (1941), who sought to extend knowledge of the complexities of agglutinin M in man and other primates by studying the reactions of human and animal bloods with anti-rhesus sera prepared by the immunization of rabbits or guinea-pigs by the washed red cells of rhesus monkeys. The sera thus prepared were found to cause agglutination of the red cells of 85% of white persons, who were therefore designated rhesus-positive or Rh-positive for short, the remaining 15% being called Rh-negative. This startling discovery was soon followed by the significant announcement that the newly discovered antigenic properties of human red cells were the basis of intragroup transfusion reactions as the result of iso-immunization of Rh-negative recipients by previous transfusion of Rh-positive blood (Wiener and Peters, 1940).

Within a remarkably short space of time a further pronouncement of major clinical importance was made. Levine announced that the dreaded intragroup transfusion reactions of women in the puerperium were also the result of iso-immunization of Rh-negative women, and drew attention to the almost invariable association of such reactions to a first transfusion with death of the foetus or the occurrence of icterus gravis neonatorum. Levine and his co-workers (1941) brought forward irrefutable evidence that not only the liability of the mother to intragroup transfusion reactions but also the disease and death of the foetus

were attributable to the iso-immunization of the mother by Rh antigens inherited by the foetus from an Rh-positive father. Somehow the antigen which the mother lacked had gained entrance to her circulation and had brought about iso-immunization with all its attendant troubles. These are the fundamental clinical facts about Rh incompatibility. Whatever advances have since been made or may be made in future, nothing can dim the brilliance of the achievements of our American colleagues, especially Wiener and Levine, in making these fundamental and fruitful observations.

Opportunities for iso-immunization of the pregnant woman by a foetal red cell antigen which she herself lacks is present in very many pregnancies—nearly 40% within the Rh group alone, according to Stancu, Clark, and Snyder (1947), but fortunately iso-immunization takes place only rarely. Clearly some red cell antigens are more effective immunizing agents than others, and also some women appear to be more readily immunized than others. Although the foetus has an A or B antigen which the mother lacks in about one-third of all pregnancies in this country, the ABO antigens only very rarely give rise to haemolytic disease of the foetus. None of the explanations of this freedom from ill effects in heterospecific pregnancy is wholly satisfactory, but clearly some potent protective mechanism must exist. There is also evidence that this protection is partially effective in preventing haemolytic disease due to coincident Rh incompatibility, for the incidence in heterospecific pregnancy is only about one-half of that found where the ABO groups of mother and foetus are compatible (Levine, 1943; Race, 1944; Wiener, 1945; Cappell, 1946). Transfusion of Rh-positive blood to an Rh-negative female before the first pregnancy has a very adverse effect and greatly increases the probability of haemolytic disease in the offspring, even if the transfusion has been given many years previously.

During the past year the Glasgow and West of Scotland Blood Transfusion Service under Dr J Wallace and Mr Milne, to whom I am indebted for these figures, has examined the blood of approximately 25,000 women from the antenatal clinics of the area, among these were 4,540 Rh-negative women, 56 of whom were proved to have Rh antibodies, and in addition two Rh-positive women were found to be immunized and to have anti-E agglutinins of low titre. No fewer than 28 of the 56 Rh-negative mothers belonged to Group A and only 18 to Group O, a striking reversal of the A/O ratio for Scotland (Cappell, 1947b). Twenty-five of the fathers were examined and an equally striking disproportion in the opposite direction was found: only five out of 25 being of Group A and 15 out of 25 of Group O. These figures are consistent with previous findings that heterospecific pregnancy appears to confer some degree of protection against Rh sensitization.

\*Read in opening a discussion in the Section of Pathology and Bacteriology at the Annual Meeting of the British Medical Association, Cambridge, 1948.

### Varieties of Haemolytic Disease

In the absence of previous transfusion with Rh-positive blood iso-immunization of the Rh-negative mother rarely occurs during the first pregnancy to an extent sufficient to produce haemolytic disease in the first-born, but the second or subsequent Rh-positive offspring may be affected. Contrary to expectation statistical analysis shows that in affected families the first recorded manifestation of the disease is usually one of the severer forms. When the haemolytic disease occurs in the second pregnancy it is more likely to take the form of icterus gravis or hydrops than congenital haemolytic anaemia, which is seen more often when the first affected child comes later in the family—e.g. the fifth or sixth. If icterus gravis appears first, it is likely to be more severe in the next affected child or it may be followed by hydrops. Only rarely, however, do the harmful effects begin with mild congenital anaemia and progress with increasing severity in successive pregnancies through icterus gravis to hydrops foetalis. This early occurrence of the severer forms of the disease seems to indicate a notably greater susceptibility to immunization on the part of some women, thus cases with an early history of hydrops rarely show strong agglutinating antibodies but have usually developed blocking antibodies instead. Others may show strong agglutinating antibodies for some years, but in subsequent pregnancies blocking antibodies may appear (Cappell, 1947a, Case 4). Although we cannot predict with certainty the type of foetal disease from the type of antibody present, there is no doubt that the presence of blocking antibodies in high titre is a bad prognostic sign and is likely to be associated with premature death of the foetus or hydrops. In my own series of frank haemolytic disease cases with incomplete antibodies were about twice as numerous as cases with only agglutinins if we discount those in which agglutination occurred only in the first or second tube, where the protein concentration was high enough to lead to agglutinative effects with blocking antibodies (Wiener's conglutination reaction). Many of these earlier cases were studied before blocking antibodies were known, and their exact nature cannot now be ascertained. Sacks, Kuhns, and Jahn (1947) found among 12,140 unselected antenatal cases 96 Rh-negative sensitized mothers, of whom 65 had blocking antibodies alone, 23 had agglutinins alone, and eight had both types of antibody.

In Glasgow, however, among the above 56 Rh-negative sensitized women encountered in routine antenatal studies 33 showed anti-Rh agglutinins in a titre of 1 in 4 or more, while 23 showed blocking antibodies or a mixture of both types. The number of Rh-negative women showing sensitization is small, only about 1 in 80, but the antenatal clinics have an excess of primigravidae, who would be expected to produce infants free from haemolytic disease. Dr Sandison, director of the East of Scotland Blood Transfusion Service, Dundee, has kindly supplied me with her recent figures showing that among 35 cases 23 had agglutinins of a titre greater than 1 in 4 and 12 had only blocking antibodies.

### The Antigenic Structure of the Rh Group

The Rh group consists of eight principal Rh types, but there is evidence that variants of these types occur. Four of the principal Rh types are Rh-positive and four are Rh-negative. These types have been recognized by the reactions of the red cells with four different antisera, from which it is clear that each Rh type consists of three elementary antigens selected from three allelomorphous pairs. The true complexity of Rh antigenic structure was first recognized by the brilliant analysis and synthesis of R. A. Fisher, who recognized that the reactions of red cells with two of the four antisera were antithetical and supposed

that they distinguished allelomorphous antigens, which called C and c. Since the reactions of the other two sera were not antithetical he supposed that they too reacted with elementary antigens and that each had an allele, these he named D or d, and E or e. Each Rh type was seen to be composed of three elementary antigens determined by three closely linked genes on the Rh chromosomes. The Rh types may thus be represented either by Wiener's shorthand notation such as  $R_1$ ,  $R_2$ ,  $R_0$ ,  $R_z$ ,  $r'$ ,  $r''$ ,  $r_x$  and  $r$  or by Fisher's more precise terminology using the CDE notation. As a result of the gradual advance in knowledge Wiener has had to admit that the Rh types consist of three elementary antigens, but he prefers to use a somewhat cumbersome terminology in which the c d e antigens are designated  $hr'$ ,  $Hr$ ,  $hr''$ . Wiener thus distinguishes four Rh types, four rh types, and three Hr types, but the relationships of these are not self-evident. I do not think we need concern ourselves here with controversies about nomenclature, but it is important to emphasize that whatever they may be called all writers recognize that each Rh type is made up of this antigenically complex pattern.

Comparison of Rh Nomenclature

Wiener's Short Notation	Wiener's Full Notation	Fisher's Notation	
$R_0$ $R_1$ or $R_1^{01}$ $R_2$ or $R_2^{02}$ $R_z$ or $R^{01}$	$hr$ $Rh_0$ $hr'$ $rh'$ $Rh_1$ $hr''$ $hr$ $Rh_2$ $rh''$ $rh$ $Rh_z$ $rh''$	$cDe$ $CDe$ $cDE$ $CDE$	Rh positive
$r'$ $r''$ $r_x$ or $r''$ $r$	$rh$ $Hr_0$ $hr'$ $hr'$ $Hr_1$ $rh''$ $rh$ $Hr_2$ $rh''$ $hr'$ $Hr_z$ $hr''$	$Cde$ $cDE$ $CdE$ $cde$	

### Criteria of Rh-positive or Rh-negative

In the assessment of the Rh group of the mother and family all individuals who lack the Rh antigen detected by the original anti-rhesus immune sera (Fisher's antigen D) should be reckoned as Rh-negative (Cappell, 1944, 1945), because such persons are liable to become immunized on suitable exposure to antigen D irrespective of whether they exhibit one or other of the associated antigens which were revealed later in man—i.e., Fisher's antigens C and E. The C and E antigens occasionally give rise to iso-immunization, especially when associated with D, but only very rarely give rise to trouble by themselves. Their presence in the mother's genotype, however, does not in any way protect her against immunization by the common Rh antigen D, and several such instances have been reported as examples of haemolytic disease in the offspring of Rh-positive mothers. It must be strongly emphasized that persons of such genotype as  $Cde/cde$  ( $r'r$ ) or  $cdE/cde$  ( $r''r$ ) are Rh-negative, and most of the more experienced workers have since agreed with me on this mode of classification (Cappell, 1944, 1945).

The Rh antigens C, D, and E are quite distinct immunologically from their alleles c, d, and e and also from one another. Each is capable of absorbing the homologous antibody from naturally occurring or artificial mixtures of Rh antibodies. It has, however, recently been found that the elementary antigens designated C, c, D, and E are not identical in all persons, and that the antisera to which they give rise are not of uniform reactivity. This lack of homogeneity was first clearly defined by Callender and Race (1946) in their recognition of the variant of C known as  $C^W$  by means of an iso-immune serum derived from a transfusion reaction, and more recently  $C^W$  has been found also to give rise to iso-immunization in pregnancy (Lawler and Van Loghem, 1947). Race, Sanger, and Lawler (1948) have reported a series of alleles at the C locus of which two are variants of C—namely,  $C^W$  and  $C^U$ —and one is a

variant of c—namely,  $c^v$ . The state of affairs at the D locus is similar. Stratton (1946) first recognized a different type of D antigen— $D^U$ —by the observation that the cells in question failed to react with certain anti-D sera which were powerful against most D-containing cells. Race and his co-workers (1948b) have extended these observations and have shown that there are more than two types of D. By titration methods they have found that anti-D sera can be arranged in a certain order of reactivity, some sera agglutinating nearly all D cells while others fail to react with certain samples which are nevertheless readily sensitized by blocking anti-D sera, and are thus presumed to contain an antigen of the D class. Dr Butler and I have observed at least two variants of D, one of which we detected in the cells of three out of 15 West African negroes. Such variants of D are probably attributable to the so-called intermediate genes which Wiener has reported among American negroes.

### The Inheritance of the Rh Group

The Rh, like other blood groups, is inherited on Mendelian principles, the genes being carried by a chromosome pair different from those carrying all the other known blood groups. There are therefore three classes of persons, the homozygous Rh-positives (RhRh), the heterozygous Rh-positives (Rhrh), and the homozygous Rh-negatives (rhrh). The prognosis in any family in which haemolytic disease has appeared depends largely on whether the father is *homozygous*, when all his subsequent children are likely to be affected, or *heterozygous*, when one-half of the offspring are likely to be Rh-negative and thus escape harm. There are a few recorded instances of the Rh-positive child of an immunized Rh-negative mother remaining unaffected by haemolytic disease, but in some of the published cases the genotyping of the child is insufficiently detailed to prove that antigen D was present, and some such children have been  $r'$  (Cde) or  $r''$  (cdE) and thus wrongly reckoned as Rh-positive. The use of Rh antisera containing two agglutinins—anti-C+D and anti-D+E (Wiener's anti-Rh, and anti-Rh)—for testing the baby's cells can easily lead to the wrong classification of infants as Rh-positives when in fact the positive reaction is due merely to the presence of antigen C or E. In some families Rh antibodies may appear in the mother and may even cause the infant's cells to give a positive direct reaction with Coombs's test, yet the child may remain clinically well or show only a trace of jaundice or anaemia. It is thus difficult to say on serological grounds that a child is unaffected if in fact its cells are sensitized, but no doubt the clinicians would be disinclined to accept such mild effects as examples of haemolytic disease. A discrepancy between laboratory and clinical findings may thus appear, but it will often be found in such families that subsequent Rh-positive children are affected beyond any clinical doubt, and this phenomenon may be merely evidence of commencing sensitization.

*Example 1*—The difference in the prognosis with a homozygous father as compared with a heterozygous father is shown in the following family history.

Two Rh-negative sisters (rhrh) married Rh-positive men related as uncle and nephew. Both became immunized by three Rh-positive pregnancies and haemolytic disease appeared in the third Rh-positive child. One man was homozygous RhRh, with the result that the fourth, fifth, and sixth pregnancies resulted in stillbirths, whereas the other man was heterozygous Rhrh and his family of seven consisted of two Rh-negative children, a normal Rh-positive child, a second healthy Rh-positive child, two Rh-negative children, but the seventh pregnancy was again Rh-positive and resulted in haemolytic disease.

*Example 2*—The late development of iso-immunization is shown in the following case for details of which I am indebted to Dr Sandison.

Mrs D, group A, Rh-negative, had a family of 17 children 15 of whom are alive and well—four are known to be Rh-negative and eight are Rh-positive. Recently an 18th child was apparently normal at birth, but its cells were strongly sensitized to Coombs's direct test, jaundice did not develop, and the child remained well, but by the 20th day its haemoglobin had fallen to 73%. The mother's serum contained only blocking antibodies.

*Example 3*—Late sensitization, perhaps induced by transfusion.

Mrs P, group O, Rh-negative, had seven normal children but received a blood transfusion in 1940 on account of haemorrhage after the birth of the seventh child. Four years later an eighth pregnancy terminated in a full-term male child who developed icterus gravis but recovered after transfusion of Rh-negative blood. The mother's serum contained blocking antibodies.

*Example 4*—This family was important in our early work, as it was our first indication that there were different kinds of anti-Rh sera and that the Rh factor was more complex than had been realized, it also illustrates that Rh-negative women of genotype Cde/cde may become immunized against D.

Mrs H, after losing her second and third children from icterus gravis, gave birth to a normal male child whose cells were agglutinated by some anti-Rh sera but not by others. Her serum contained a moderate amount of agglutinating anti-D, which reacted with the cells of her husband and first child but not with the cells of the fourth child. Later, the fifth and sixth children were also unaffected and proved to be Rh-negative cde/cde. The mother herself and the fourth child are of type Cde/cde ( $r'$ ) and thus might have been called Rh-positive by some observers.

The better understanding of the pathogenesis of haemolytic disease has not as yet yielded any notable advance in prophylaxis, and no effective means has been found either to prevent iso-immunization of Rh-negative women by Rh-positive fetuses or to render the effects of Rh antibodies less harmful. Karher (1947) has reported that three sensitized women who had previously lost children from haemolytic disease were treated with repeated intramuscular injections of ethylene disulphonate in homoeopathic doses during a subsequent pregnancy. Their antibody titres fell markedly and each gave birth to a living Rh-positive child, two were unaffected and the third recovered under treatment. Confirmation of such interesting results is highly desirable.

### Cerebral Damage

Hydrops foetalis is usually regarded as universally fatal, but I understand that Diamond has obtained a few survivors from the mild form after treatment by replacement transfusion. Icterus gravis neonatorum has a high mortality if untreated, but the use of Rh-negative blood for transfusion of the newborn infant has greatly improved the prognosis. Some very experienced workers, however, have expressed doubts about the value of treatment on account of the risk of cerebral damage (nuclear jaundice) and the chances of prolonging the lives of infants who are hopelessly crippled mentally or physically. I have thought it worth while therefore to report the late results of cases treated by Dr McFarlane and me before 1945 and of others subsequently treated by Dr Sandison, to whom I am indebted also for the results of the follow-up.

We have been able to re-examine 30 infants treated by transfusion of Rh-negative blood immediately after birth or mainly within the first 12 hours, all are normally developed physically and mentally, and not a single child shows evidence of backwardness. In comparison I am indebted to my colleagues of the Royal Hospital for Sick

Children, Glasgow, and particularly to Dr R R Gordon, for the information that in a follow-up of a larger series of cases of icterus gravis admitted to that institution between 1934 and 1944 and treated mainly at a later stage by transfusion of blood not selected for Rh factor about 12% showed some residual nervous sequelae, such as general backwardness, a figure in close agreement with those given by Parsons (1947). Dr G L Montgomery, pathologist to the Royal Hospital for Sick Children, Glasgow, informs me that during the same period the incidence of nuclear jaundice in fatal cases of icterus gravis was about 30%, a frequency notably higher than that of clinical signs of nervous involvement.

There is no doubt that nuclear jaundice may be unsuspected clinically in cases dying within the first few days. I am not convinced that the cerebral damage which results in nuclear jaundice occurs before birth, its incidence is so irregular and so poorly correlated with the amount or type of antibodies or the intensity of jaundice or anaemia that one is driven to speculate about other possible factors. In some cases observed personally I have been impressed with the difficulty in establishing respiration after birth, and perhaps anoxaemia in the immediately post-natal period may be a determining factor. While one must agree with Parsons (1946, 1947) that it is useless to prolong the life of the child known to be afflicted with nuclear jaundice, I am more optimistic than he, and I am hopeful that it may be possible at least to reduce the incidence of nervous sequelae by prompt and efficient treatment. Whether immediate replacement transfusion is the method of choice for this purpose, as Wallerstein (1946) and Wiener, Wexler, and Grundfast (1947) claim, can be decided only when a large series of cases has been treated by this technique.

In my opinion there is no evidence to suggest that Rh incompatibility between mother and child will itself lead to mental deficiency. General mental backwardness may result from damage to the cerebral cortex in those who have suffered from icterus gravis in the neonatal period, and if the basal nuclei have been severely damaged motor disturbances are very likely to follow in the survivors. The view of Yannet and Lieberman (1946) that mental deficiency occurs as the sole clinical manifestation of Rh incompatibility has not been borne out by subsequent studies (Scholl, Wheeler, and Snyder, 1947; Cappell, 1947a).

## PRELIMINARY NOTE ON INFLUENCE OF HETEROSPECIFIC IMMUNIZATION ON PRODUCTION OF Rh ANTIBODIES

BY

J J VAN LOGHEM, MD

With the Technical Assistance of Miss M v d Hart and  
A Poelenjee

(From the Centraal Laboratorium van den  
Bloedtransfusiedienst Binnengasthuis Amsterdam)

In a previous paper (van Loghem, 1947) we reported the results of artificial immunization of male volunteer donors by frequent injections of small quantities of R' (Cde) and R'' (cdE) cells given intravenously in order to produce Rh agglutinins anti-C and anti-E. In two of the six volunteers the results were satisfactory. Rh agglutinins were formed in sufficient quantity to obtain useful Rh test sera. After the first experiments we were able gradually to extend the group of six male donors to 17. In general it takes a long time before the donors react with the formation of antibodies after repeated injections, and many of them do not react at all on the intravenous administration of these weak antigens (C, D, and E). Therefore we tried the influence of heterospecific immunization on the production of Rh antibodies.

It is a well-known fact that immunization with variola vaccine, typhoid vaccine, and many other vaccines may increase the titre of iso-agglutinins  $\alpha$  or  $\beta$ \*. We tried this time to stimulate the production of Rh antibodies by simultaneous injections of two or three other antigens as well as the Rh antigens, where Rh antigens alone failed to act after prolonged administration. The vaccines used for this purpose were tripiovaccine (1,000 million typhoid bacteria, 500 million paratyphoid A bacteria and 500 million paratyphoid B bacteria per ml) and tetravaccine (5,000 million cholera bacteria, 500 million typhoid bacteria, 500 million paratyphoid A bacteria, and 500 million paratyphoid B bacteria per ml).

The donors selected for this purpose had already received many injections, varying from 15 to 42 in number, without producing Rh antibodies. Their sera were investigated at regular intervals by the saline and albumin methods.

## Donor H B

H B, aged 40, blood group A rr (cde/cde), had already received 42 injections, each of 1 ml of a 25% red cell suspension. The cells used for this purpose were type A R' (CDe/cde), always derived from the same donor (see Table I). The injections were given intravenously mostly twice a week during a period of seven months, with three periods of rest varying from one month to eleven days.

When we started the administration of typhoid vaccine no Rh antibodies (early-immune or hyperimmune) were demonstrable in his serum. Tripiovaccine was given three times intramuscularly at seven day intervals in quantities of 0.5 ml, 1 ml, and 1 ml, but without results. After another nine injections with

\*Other arguments for the influence on the production of heterospecific antibodies by injection of heterospecific antigens were communicated (1) by Host (1947), who suggested that in cases of erythroblastosis foetalis, in which the mother received previous to Rh immunization by pregnancy injections of diphtheria, tetanus, other vaccine, the mortality rate of the newborn increased, (2) by Pondman (1947), who reported that the production of antidiarrhoeal serum in horses was stimulated by injections of a heterospecific antigen—tapiocta, and (3) by our personal investigations (Loghem and Spooandcr, 1948) which proved that ABO incompatibility in cases of Rh antagonism has an unfavourable influence on the clinical aspect of erythroblastosis foetalis.

TABLE I—Donor H B (Blood Group A rr)

Date	No of Inj	Quantity of A R Cells given I V (ml)	Rh Antibodies		Quantity of Triplo vaccine given I M (ml)	Quantity of Tetra vaccine given I M (ml)	
			Early-immune	Hyper-immune			
			D	D			
20/11/47	43	1			0.5		Temp
27/11/47	45	1			1.0		
4/12/47	47	1			1.0

19/2/48	62	1	1 2	1 2			

1 ml of 25% R<sub>0</sub> cells, tetravaccine was given. Following the second injection of 0.5 ml of tetravaccine, given one week after the first, clinical symptoms of sickness and rise of temperature resulted and lasted for two days.

Five days after the latest injection with tetravaccine the serum for the first time contained Rh antibodies type anti-D in low titre (1/4). Another injection with 1 ml of tetravaccine seven days later did not further increase the titre of Rh antibodies, although frequent injections of R<sub>0</sub> cells were also given.

### Donor W E

Approximately the same procedure was followed with the male donor W E, aged 19, blood group A rr (see Table II).

TABLE II—Donor W E (Blood Group A rr)

Date	No of Inj	Quantity of R <sub>1</sub> Cells given I V (ml)	Rh Antibodies				Quantity of Triplo vaccine given I M (ml)	Quantity of Tetra vaccine given I M (ml)	Temp
			Early immune		Hyper-immune

29/1/48	33	1						0.5	
1/2/48	34	1						1.0	
19/2/48	37	1	1	32	—	1	32	—	
8/3/48	40	1	1	4	—	1	4	—	
			1	4	—	1	16	—	

Before the heterospecific immunization he had received only 15 injections of R' cells of two different donors. Dām O R' (Cde/cde) and Mor A R r (Cde/cde). Up to this time no Rh antibodies had been formed. The cells of Dām should more properly be called CD<sup>u</sup>e/cde. This was elucidated by Dr Race. The finding of some anti-D besides anti-C in the serum of other Rh-negative donors injected with these cells was explained by Dr Race by the presence of the D<sup>u</sup> antigen in the cells of Dām.

The first injection of 0.5 ml of triplovaccine gave no results. The second injection of 1 ml was followed by a rise of temperature and a feeling of sickness. After another week the administration was repeated. Ten days later the serum was investigated, and Rh antibodies, type anti-C, were present in a low titre (1/2). After repeated injections with R' cells the titre increased, but only to 1/8, happily no anti-D (early-immune and hyperimmune) was formed, which could have been the result of the presence of the D<sup>u</sup> antigen in the red cells of donor Dām.

In an attempt to raise the titre further by injections of stronger antigens, tetravaccine was given on the same day as the 29th injection of R' cells. After three injections of tetravaccine at weekly intervals the titre increased to 1/32—pure anti-C agglutinins without anti-D (early-immune or hyperimmune). A few days later 1 litre of the donor's blood was replaced by 1 litre of Rh-negative blood. After absorption with B rr blood the titre fell to only 1/16. The serum is very useful as Rh test

serum. After further injections with R' cells the titre of anti-C agglutinin decreased and only some hyperimmune anti-C was formed.

### Donor G de J

This case is probably still more interesting. Male donor G de J, aged 33, blood group A rr, from March 11 to Sept 22 1947, received 32 injections of 0.25 ml of R' cells of the two donors Dām and Sch. The cells of Dām are O CD<sup>u</sup>e/cde and of Sch O Cde/Cde. After 17 injections at regular intervals anti-C agglutinins, titre 1/8, and hyperimmune anti-D, due to the presence of D<sup>u</sup> antigen, were formed.

It is remarkable that early-immune antibodies (agglutinins), type anti-D, could never be demonstrated in his serum. The generally accepted and proved theory of Diamond that hyperimmune antibodies are formed only after the production of early-immune antibodies by prolonged immunization seems not always to be true. After 14 other injections the titre of anti-C agglutinins decreased to 1/4, but that of the hyperimmune form increased to 1/32.

After four months' rest agglutinins type anti-C were no longer present in the serum of this donor, and the hyperimmune antibodies anti-C and anti-D reappeared only in a very poor titre of 1/2 and 1/1 after one injection with R' cells. We then tried the influence of heterospecific immunization. 0.5 ml of tetravaccine was given intramuscularly. The donor reacted with a feeling of sickness and a rise of temperature (38.6° C) lasting nearly two days. In the same week he received two injections with R' cells. The anti-C agglutinins reappeared in his serum, especially the hyperimmune form anti-C, which increased rapidly. As will be seen from Table III a second injection of

TABLE III—Donor G de J (Blood Group A rr)

Date	No of Inj	Quantity of O R <sub>1</sub> Cells given I V (ml)	Rh Antibodies				Quantity of Tetra vaccine given I M (ml)	
			Early immune		Hyper immune			
			C	D	C	D		
5/6/47	13	0.25	1	2				
19/6/47	17	0.25	1	8	—	1	8	
29/8/47	28	0.25	1	4	1	16		
22/9/47	32	0.25	1	4	1	32	1	8
30/3/48	33	0.25	—		1	2	1	1
5/4/48	34	0.25						0.5
8/4/48	35	0.25						
11/4/48	36	0.25	1	8	1	64	1	8
15/4/48	37	0.25	1	16	1	256	1	16
			1	32	1	512	1	32

tetravaccine and two additional injections with R' cells increased the titre of anti-C agglutinins to 1/32, the hyperimmune anti-body anti-C to 1/512, and the hyperimmune anti-D to 1/32.

### Discussion

From these three cases we may conclude that it is possible to stimulate, even to provoke, the production of Rh antibodies by heterospecific antigens after a shorter or longer course with the specific Rh antigens. This procedure is not successful in all cases. One of our first donors produced pure anti-E agglutinins (titre 1/64) after repeated injections with R' cells. Later on the titre fell in spite of many injections with the same cells and a few short periods of rest. Neither could we observe any success after repeated injections with tetravaccine. It seems that after too many injections a certain insensibility appears. It is therefore necessary to prevent overdosage.

In Table IV the final results of immunization of the 17 donors are collected—14 received tetravaccine after a longer or shorter period of Rh immunization. We have already stated that only three of them produced Rh antibodies. They all showed clinical signs of sickness and a rise of temperature. In all the other cases the clinical manifestations were absent or very slight. In two other donors Rh

antibodies were formed after immunization with Rh cells only, but in one of these a strong increase of titre was obtained only after administration of tetravaccine

In all, four (23%) of the 17 donors produced Rh antibodies—1 anti-E, 2 anti-C, and 1 anti-D. The sera derived from the first three persons were very useful as Rh test sera anti-C and anti-E.

As is shown by the above-mentioned findings it is especially those individuals who show clinical reactions to the application of triplovaccine and tetravaccine who are apt to form Rh antibodies. This was also confirmed by the serological results concerning the formation of agglutinins against typhoid and paratyphoid A and B antigens O and H.

As will be seen from Table V only those donors who produced antibodies against nearly all the injected typhoid antigens showed clinical symptoms of sickness and pro-

### Summary

About 23% of Rh-negative male donors produced type specific Rh agglutinins, some of them with titres high enough for useful Rh test serum after heterospecific immunization.

It is necessary to exclude the presence of weak antigens (D<sup>u</sup> and others) in order to prevent the formation of unwanted antibodies (anti-D).

It was proved in most cases that the occurrence of decrease in titre of early-immune antibodies anti C or anti-E was followed by increasing titre of the hyperimmune form. In one case an exception was found: hyperimmune antibodies were formed without preceding formation of early-immune antibodies.

The production of Rh antibodies is stimulated or even provoked by the administration of bacterial antigens.

In general only those persons who reacted clinically and serologically to the administration of triplovaccine and tetravaccine produced Rh antibodies.

We are very grateful to Professor Dr A. Charlotte Ruys, who kindly investigated the sera of the donors for typhoid agglutinins.

duced Rh antibodies. None of the donors reacted to the administration of cholera vaccine. This may be explained by the fact that this cholera vaccine must be a very poor antigen.

From these results it may be concluded that it is possible to change the procedure in a simple way—that is, to choose donors by injecting them with triplovaccine or tetravaccine. Only those who react clinically as well as serologically to the administration of vaccines will be selected for the immunization procedure.

Recently we started investigations with another group of volunteers (from a convent). Three nuns were injected with C<sup>w</sup> antigen, and one of them formed a pure C<sup>w</sup> antibody of the hyperimmune form after 20 injections administered over a period of three and a half months with a titre of 1 8.

Unesco has announced the formation of an international agency to aid children's villages, which are now operating in over twelve European countries for the care of war orphans. The agency has been named the International Federation of Children's Communities. This organization will co-ordinate community activities, sponsor psychological research, train personnel, raise funds, and maintain contact with Unesco, the International Children's Emergency Fund, and international voluntary agencies interested in child welfare. The federation will be served by an international co-ordinating committee and secretariat, with headquarters at Trogen. Committee members include Dr. Préaut, director of the Hameau Ecole, Ile de France; Professor Ernesto Codignola, director of the Scuola Città Pestalozzi, Florence, Italy; Mr. Arthur Bill, educational director of the Pestalozzi Village, Trogen, Switzerland; Mr. René de Cooman, president of the Marcelline Children's Village, Charleroi, Belgium; and M. Henri Julien, director of the République d'Enfants, Moulin Vieux, France. Two places have been left open for village directors from Eastern European countries. Dr. Préaut has appealed for world wide support for the villages so that the many thousands of war orphans may be restored to physical and mental health. The agency is setting up centres in Europe and America to receive funds and much needed equipment. This includes books and other school supplies, sports gear, model toys, cinema cameras and projectors, laboratory supplies, and equipment for raising food on the village farms. Information about the receiving centres may be obtained from Unesco's Reconstruction Department, 19, Avenue Kléber, Paris 16, or from the Commission for International Educational Reconstruction, 744, Jackson Place, N.W., Washington, 6.

# HOW IMPORTANT IS TRANSFUSION AS A CAUSE OF HAEMOLYTIC DISEASE OF THE NEWBORN?

BY

GEORGE DISCOMBE, M.D., B.Sc.

AND

H. O. HUGHES, OBE, MRCS, LRCP

(From the Central Middlesex County Hospital)

When transfusion reactions caused by the Rh factor were first recognized (Wiener and Peters, 1940) it was thought that sensitization by transfusion was rare, though once it had developed following repeated pregnancy small transfusions would increase the antibody titre. Attention was therefore directed to the peculiarities of those patients who formed antibodies, and it was thought that subjects suffering from certain diseases (Drummond *et al.* 1945, Calendar and Paykoc, 1946) were especially apt to produce antibodies to antigens which they lacked. Studies on soldiers transfused during the invasion of Europe led to a change of opinion, Moloney (1945), Hattersley (1947), and Diamond (personal communication, 1947) showing that at least 55% of Rh-negative\* males were sensitized by a single transfusion of Rh-positive\* blood, while Wiener and Gordon (1947) sensitized five out of nine volunteers, obtaining high titres in two.

Since Levine and others (1941a, 1941b) had shown that haemolytic disease of the newborn is caused by a reaction between a foetal antigen and the corresponding antibody formed by the mother, and that in about nine-tenths of all cases the antigen concerned is the Rh antigen, it becomes important to decide what part transfusion plays in the pathogenesis of haemolytic disease of the newborn. Various authors have noted that transfusion occasionally preceded and apparently caused fatal cases of disease in a first-born child, but Hellmann (1947) studied 27 Rh-negative mothers who had given birth to affected infants and found that seven had been transfused with blood of unknown Rh type before the birth of the first affected infant, whereas only 2% of the generality of mothers had been transfused.

## Present Investigation

To compare with these results, the notes of Rh-negative mothers of affected infants born or treated in this hospital were reviewed. The mild cases not clinically distinguishable from "physiological jaundice" were rejected, as were those due apparently to ABO compatibility, but two cases without serological data were retained—these mothers had never received a transfusion. Mothers who had received only Rh-negative blood were classed as "not transfused." Those patients whose hospital notes were not explicit were written to, and all replied. The results are given in Table I together with the replies of 200 consecutive mothers attending the antenatal clinic, who are described as "unselected." In Table II is shown the mortality of the infants in the two groups into which the mothers of affected infants are placed.

The frequency of transfusion with blood which had not been Rh grouped is therefore 36% among the mothers of infants affected by haemolytic disease of the newborn, compared with 2% among the general population of the clinic. These results could be explained by either of two hypotheses: first, that mothers who gave birth to infants

\*Throughout this paper Rh positive refers to blood possessing the antigen D, and Rh-negative, in the case of recipients, refers to those lacking this antigen, in the case of donors, Rh-negative implies lack of the three major antigens, C, D, and E.

affected by haemolytic disease are particularly liable to illness which requires transfusion—a hypothesis for which there is no evidence whatsoever, or secondly that transfusion sensitizes the recipient and thus prepares the way for the development of haemolytic disease—a view for which there is plenty of support.

This risk has been recognized for over a year at this hospital, and the Gunz (1946) transfusion form was modified to eliminate it (see accompanying Form). It is

a rule that no female below the age of 40 years may be transfused unless she has been Rh tested, and if found to be negative she must receive Rh-negative blood. In the rare extreme emergency, when there is no time to test, or in emergency transfusions in domiciliary work, Rh-negative blood is used until the recipient has been tested and shown to be positive. This procedure has been made possible only by the adoption of Chown's (1944) capillary technique, which usually gives a clear-cut result within 10 minutes of setting up or 15 minutes of seeing the patient (Discombe and Meyer, 1948), and by the co-operation of the newspapers which serve the locality in advertising our need for donors.

It is well known that sensitization can be induced by a single injection of quite small quantities of an antigen. There is no reason why the Rh antigen should behave differently, so it must be assumed that injection of any volume of blood, from 0.1 ml to 1,000 ml, should suffice to establish sensitization. The titre of antibody produced by a single injection will be low, but will rise rapidly if the antigen is again injected after a lapse even of years.

Since for many years the intramuscular injection of parental blood has been recommended for the treatment of haemorrhagic disease of the newborn, it appears useful to calculate the frequency with which this procedure might sensitize the infant to the Rh factor. Of the whole population, about 17% are Rh-negative (rr) and 45% heterozygous Rh-positive (Rr). Rh-negative infants can be born to Rh-positive parents in the matings  $Rr \times rr$ , constituting 15.2%, and  $Rr \times Rr$ , forming 19.8% of all matings. Therefore, in the first group three out of four and in the second group one out of four of all children will be Rh-negative, so that one or both parents are Rh-positive when the infant is Rh-negative in about 12.5% of all births. It seems that over 6% of all infants could be sensitized by the injection of parental blood.

If all infants were treated thus, about one in three of all Rh-negative females would be sensitized. Fortunately, haemorrhagic disease of the newborn is not common, but, even if it is rare, treatment by injection of parental blood will sometimes result in the appearance of haemolytic disease in the first-born of an Rh-negative mother. Such possible tragedies can be avoided by the use of a vitamin-K analogue, and the use of parental blood in its place will no doubt in future be regarded as a barbarous and unethical procedure.

### Conclusion

A history of having received a blood transfusion without special precautions for Rh matching is 18 times more common among mothers of infants suffering from haemolytic disease of the newborn than among unselected patients at the antenatal clinic.

Such transfusion probably causes the disease.

Injection of paternal or maternal blood into an infant without Rh matching would sensitize about one in three of the Rh-negative females at risk.

It is wrong to inject any female with blood from another individual unless either the recipient is known to be Rh-positive, both recipient and donor to be Rh-negative, or the recipient to be too old to bear children.

This rule must be broken only if the patient is expected to die before Rh-compatible blood can be obtained.

We wish to acknowledge our debt to the staff of the department of obstetrics for much valuable help and advice, and for permission to review large numbers of their case records.

As the result of negotiations between the Northern Ireland Ministry of Health and the Northern Ireland Pharmaceutical Negotiating Committee, the Committee has decided to recommend all chemists in Northern Ireland to enter the Health Service provisionally, pending the outcome of further negotiations. The Minister of Health (said an agreed joint statement) "undertook to appoint a practising accountant to carry out an investigation into dispensing costs in Northern Ireland and, after receiving the Accountant's report, to enter into further negotiations on the basis of this report and that made by the accountants appointed by the chemists, full account to be taken of pharmaceutical practice in Northern Ireland."

## THE EVOLUTION OF GASTRIC AND DUODENAL ULCERATION

BY

J. DONALDSON CRAIG, MD, M.R.C.P.

Research Fellow in Medicine St Mary's Hospital  
Medical School

Acquired disease being the product of disharmony between constitutional and environmental factors, it is inevitable that alterations in mode of life should be accompanied by change in the pattern and distribution of certain diseases. As a preliminary to the present investigation the early literature dealing with peptic ulcer was reviewed and the observations thereon summarized in a previous communication (Craig, 1947). Space will not permit of further detailed discussion of the nature and incidence of peptic ulceration before the present century, but certain broad conclusions may be outlined.

Although gastric ulcer was mentioned by Celsus and was well recognized in the eighteenth century, the disease does not appear to have been at all common until the middle of the nineteenth century, when William Brinton (1857) concluded that about 5% of the population were subject to gastric ulcer at some time or other in their lives. At that time gastric ulcer was predominantly a disease of young women, many of whom suffered from perforation. Haematemesis occurred more commonly in men, generally in the fifth decade, but by the end of the century this complication, too, was one more often affecting young women (Hale White, 1901). Thus, although the overall incidence of gastric ulcer has remained fairly uniform during the past century, the age and sex distribution and its clinical pattern have changed very considerably in that time.

George Hamberger (1746) first described a case of duodenal ulcer, and Abercrombie (1828) gave the first account of the clinical features of the disease, but until the end of the century the amount of interest taken in the condition was out of all proportion to the number of cases encountered. The Fenwicks (1900), for example, were able to quote over 200 references, yet for all their extensive experience and keen interest they could gather together only 68 cases, 25 of them acute ulcers. It is generally believed that the apparent rarity of duodenal ulcer until the present century was the consequence of failure to recognize the condition. Undoubtedly many cases were missed, but when the situation is viewed against the broader background of earlier writings it is difficult to escape the conclusion that improvement in diagnosis was concomitant with an increase in the frequency of the disease. Review of more recent years provides strong evidence of further increase, and this suspicion becomes stronger. Although there is every reason to believe that duodenal ulcer has become very much more common there is no evidence that its clinical features have altered in any way.

Pringle (1753) and MacGregor (1804) in their treatises on military medicine made no mention of dyspepsia in the Army. In the war of 1914-18, digestive diseases of all types were no great problem, but in the recent war, by the end of 1941 no fewer than 23,754 serving personnel had to be invalided from the Army alone on account of peptic ulcer, duodenal ulcer preponderating over gastric ulcer in the ratio of approximately 7:2.

The changing nature and frequency of gastric and duodenal ulceration thus becomes apparent. The evolution of acute gastric ulcer, of chronic gastric ulcer, and duodenal ulcer has been so different as to raise the strong suspicion that they may be distinct diseases, albeit, to one another. In an attempt to evaluate causal factors

it should not therefore be too readily assumed that gastric ulcer differs from duodenal ulcer only in its situation

### Statistics of the Registrar-General

Tidy, by analysis of the statistics of the Registrar-General for the years 1911-37, has shown that the increase in the crude death rate from peptic ulcer during this period is accounted for largely by the increase in deaths from gastric ulcer in men over 40. He has also pointed out the rapid diminution in the number of deaths from gastric ulcer in women under the age of 40. Jennings (1940), in a comprehensive historical survey of perforated peptic ulceration, has stressed the changing age and sex distribution of this condition, with particular reference to the period 1901-35.

In this present review death rates in the civil population have been analysed in selected years, up to and including 1945. The difficulties inherent in the interpretation of these figures are manifold, and in the past have perhaps been insufficiently stressed. Acceptance of these statistics as accurate implies an assumption that the great majority of death certificates correctly assign the cause of death, and this is a bold surmise when dealing with two diseases—gastric and duodenal ulceration—which are so readily confused with one another and the latter of which was widely recognized only recently. Secondly, such statistics refer to only a small proportion of ulcer sufferers—some 5% or so—who die from the direct effects of their ulcers. Finally, in trying to assess disease trends, it is almost impossible to evaluate the effect of therapeutic changes.

From the year 1940 a change was made in the manner of selecting the assigned cause of death where more than one cause was mentioned in the death certificate, the choice then being "that in the main inferred from the statement of the certifier instead of being determined by arbitrary rules of precedence." This change had the effect of producing an apparent increase of about 4% in the mortality rate of peptic ulcer. If the crude death rate for all forms of peptic ulcer be plotted graphically for the years 1910-45 it will be noted that no very significant fluctuation occurred between the years 1911 and 1921, after which there was a very sharp and uninterrupted rise till 1927. From then

until 1939 this rise was less marked and was interrupted by minor falls, but the year 1940 saw the sharpest rise hitherto recorded, the rate remaining at the same high level in 1941, falling back to its original level in 1942, and then rising steadily and fairly steeply till the year 1945. Only about one-fifth of the increase in 1940 could be accounted for by the new method of selecting the cause of death.

In Fig 1 the death rates from gastric ulcer and duodenal ulcer are plotted separately for the two sexes. From 1940 onwards the figures are based on the new method of assessment; before 1935 they are based on the old method. For the years 1935-9 inclusive two sets of figures are plotted—those based on the old method and those based on the new method. It will be seen that the change in the method of assigning the cause of death

makes no significant alteration to the general trend. The increased mortality rate is accounted for largely by the increased death rate from gastric ulcer in males and to a smaller extent from duodenal ulcer in males. Although duodenal ulcer in females has been a steadily increasing cause of death the mortality rate from gastric ulcer in women has fallen fairly steadily and uninterruptedly, with the exception of the year 1940, when there was a significant rise in the death rate from both forms of ulcer in both sexes. At all times, in both sexes, gastric ulcer has been a commoner assigned cause of death than has duodenal ulcer.

### Population Trends

It is pertinent to determine how far these fluctuations in crude mortality rates represent a response to alterations in the age distribution of the population. It is common experience that the mortality from perforation, haemorrhage, and operation increases with age. Analysis of the figures for the year 1945 shows that the death rate from all forms of ulcer increased steadily with age (Fig 2). By plotting graphically the proportion of the population (a) over the age of 45, and (b) over 65, one can demonstrate that these older sections of the community are increasing steadily. Similarly, it may be shown that an increasing proportion of ulcer deaths occur in these two older groups, and in the following table the population distribution during the years 1911 and 1942 is compared.

	1911	1942
Proportion of population over 45	21%	35%
all peptic ulcer deaths over 45	37%	90%
Proportion of population over 65	5%	10%
all peptic ulcer deaths over 65	10%	31%

FIG 1—Crude death rates per 100,000 living for gastric ulcer and duodenal ulcer from 1905 to 1945. During the periods of the two world wars non-civilian figures are excluded. For the years 1935-9 inclusive the graphs show rates (a) based on the revised method of assignment (o-o-o) and (b) based on the old method of assignment (x-x-x).

FIG 2—Civilian death rates per 100,000 living from gastric and duodenal ulcers in both sexes at various ages, for the year 1945. In male Service personnel at all ages in this year the corresponding rates were DU 12, GU 15, per 100,000 living.

It is therefore apparent that the increase in the death rate in the older groups is out of proportion to their greater numbers and that the brunt of the overall increased death rate is being borne by these older people, but these figures alone give no indication of changing death rates in the other sections of the community

Accordingly, death rates for gastric ulcer and for duodenal ulcer per 100,000 living were plotted in various age and sex groups for selected years from 1911 to 1945, inclusive. Limitations of space will not permit publication of all these graphs, but their trends will be briefly summarized

**General**—In both sexes and all age groups gastric ulcer has proved a more common assigned cause of death than has duodenal ulcer, despite the fact that in all carefully investigated modern series duodenal ulcer is much commoner than ulcer in the stomach. This may argue a higher mortality rate from gastric than from duodenal ulcer, but it may be only a reflection of the tendency of many practitioners to refer generically to a 'gastric ulcer' whether the lesion be in the stomach or the duodenum. None the less, the view that gastric ulcer is more commonly fatal than duodenal ulcer is in accord with the military figures for 1940-2 and gastric ulcer deaths in the Services during the year 1945 again preponderated over duodenal ulcer deaths in the proportion of 5 to 4. These rates are lower than those in the corresponding civilian group owing to the medical selection before enlistment and the early invaliding of sufferers

**Death Rates in Males Under 45**—These curves show the fluctuations which inevitably occur when fairly small numbers are being considered. Although the death rate from both gastric and duodenal ulcer did not vary greatly between the years 1915 and 1939, it is perhaps significant that the therapeutic advances made during this period did not result in any appreciable lowering in mortality in this group. No weight can be attached to the rise during the war years, for these figures refer only to the civilian population, which then contained an abnormally high proportion of unfit men rejected for military service

**Death Rates in Older Men**—Some of these are charted in Fig 3, which demonstrates the increasing incidence over the period reviewed, the increasing mortality with age, and the greater mortality from gastric ulcer than from duodenal ulcer

**Death Rates in Women**—The outstanding feature of these curves is the remarkable fall in gastric ulcer mortality in all except the very oldest (Fig 4). The death rate from duodenal ulcer has always been small, and it has remained fairly constant in particular age groups, the overall increase in such mortality (Fig 1) resulting very largely from the ageing nature of the population

Fig 3—Male death rates per 100,000 living from gastric and duodenal ulcer in selected years from 1911 to 1945, in the age groups 45-55 and 55-65, non-civilian males are excluded in the years of the two World Wars

Fig 4—Female death rates per 100,000 living from gastric ulcer in various age groups for selected years from 1911 to 1945, non-civilian females being excluded in 1942 and 1945

### The Changing Incidence of Perforation

Although in the year 1945 the mortality from both duodenal and gastric ulceration in both sexes increased with age, corresponding analysis of deaths for the year 1919 (Fig 5) showed a high peak of mortality from gastric ulcer in young women. The lowering of the death rate in the young women is the result of the virtual disappearance of gastric perforation in this group. In 1907 Hawkins and Nitch, reviewing 556 cases of gastric ulcer treated at Thomas's Hospital, gave details of 92 cases of perforation, only 30 of which occurred in men. In this series perforation in men occurred most often over the age of 40, in women the great majority of cases occurred between the ages of 15 and 25. The curve obtained by plotting these cases in age groups is substantially the same as that derived from charting the details of Brinton's (18 cases of 199 perforations, only 60 of which occurred in men). From the details accompanying this communication of Hawkins and Nitch it appears that at least half the ulcers which perforated in young women were chronic in character, the perforations being preceded by a long history of dyspepsia and the ulcer bed being scarred. The age-and-sex incidence of peptic perforation is in striking contrast to the experience of Illingworth, Scott, and Jamieson (1946), who reviewed 880 cases of perforation occurring between 1938 and 1943, 95% of them in men, the perforation being in the duodenum in 87% of cases. In their series the commonest age at perforation was between 35 and 50.

Fig 5—Death rates per 100,000 living from gastric ulcer and duodenal ulcer in various age groups for the year 1911

These findings tally closely with figures collected by Boggan, by Forty (1946), and in a series at St Mary's Hospital over the past ten years. That Illingworth's series consisted almost entirely of chronic ulcers is indicated by the fact that in the absence of medical treatment a great majority of cases relapsed within five years, some 20% of them suffering further major complications.

All earlier works consulted agree on the age-and-sex incidence of gastric perforation, but the only series of perforated duodenal ulcer found after prolonged search is the small one collected from the literature by Moynihan and published by him in 1905. The relative rarity in females is apparent, and it seems that on the whole these perforations occurred at an earlier age than those in the series of Illingworth *et al*. The difference, however, is not sufficient to be significant.

Apart from the evidences of the changing nature of gastric ulcer in women, the most striking features of these analyses are

- 1 The striking proof of the ageing nature of our population
- 2 The evidence of increased mortality in the older age groups
- 3 The steady rise in total peptic ulcer deaths between the years 1921 and 1939, with a well-marked sudden increase in 1940 and 1941, this increase affecting the mortality from both gastric and duodenal ulcer in both sexes and all age groups. It has been pointed out by Illingworth that there was a marked increase in the incidence of perforation in the autumn of 1940 and the spring of 1941—that is, at the time when the real seriousness of the late war was first brought home by the defeat of the French armies and the bombing of this country. As Illingworth has further pointed out, this prevalence of perforation was not confined to areas subject to aerial bombardment. It is, however, legitimate to infer that the nervous strain and anxiety engendered by circumstances was nation-wide. The 1942 fall in death rate is the most pronounced during the period of observation. The explanation is perhaps that the circumstances which produced the rise in 1940 and 1941 advanced the death of some who might otherwise have survived till 1942 or 1943, and the population during these latter years therefore contained relatively fewer of the less hardy elements.
- 4 The maintenance or actual increase in death rate from duodenal ulceration in all age groups despite therapeutic advances, particularly in the treatment of perforation and haemorrhage—a circumstance which suggests that the actual incidence of the disease in the population at large has undergone a considerable increase.
- 5 Only in gastric ulceration in young women has there been any striking decrease in mortality. This has been the result not of corresponding increase in medical knowledge but of some unknown evolutionary process. It is perhaps significant that chlorosis, once a frequently associated disease, has now virtually disappeared.

### Conclusions

Certain difficulties inevitably arise in the course of any attempt to trace the history of a disease. Earlier accounts are based on very imperfect knowledge, the growth of understanding having paralleled the evolution of the disease. Yet certain writings stand out, and one feels that the observations contained therein are reliable even though it may be difficult to communicate this confidence to others. The inadequacies of death-rate statistics has already been stressed, but a review of these figures affords an idea of the trend which a disease is taking. Military surveys and series of cases of perforation published at different periods strongly suggest that the pattern and distribution of gastro-duodenal ulceration have materially changed. When all the evidence from these independent sources is entirely consistent certain conclusions may be drawn.

It would appear that gastric ulceration, at least in its present form and prevalence, is a disease of comparatively recent evolution, and there is good reason to believe that

ulceration of the duodenum is a disease of even later development.

While, so far as can be ascertained, duodenal ulceration has simply increased in frequency during the period under survey, it is clear that in the case of gastric ulcer not only the age and sex distribution but even the actual nature and clinical pattern have altered considerably during the last hundred years or so, although it is probable that the total incidence has not undergone any very striking increase. In the time of William Brinton gastric ulcer principally affected women, and the ulcer seems to have been very similar to that which we encounter to-day, although a small proportion of chlorotic young women developed perforation of an acute ulcer. Haematemesis in young women was relatively uncommon, most women so affected being in their fifth decade. At the beginning of the present century chronic gastric ulcer was becoming relatively more frequent in males, but a larger number of women of child-bearing age suffered from haematemesis due to acute superficial ulceration. Gastric perforation was predominantly a disease of young women. It is difficult to determine exactly when this state of affairs altered, but it is probable that the change occurred during the period of the first world war.

In the course of the preceding investigation the changes in the incidence, distribution, and pattern of the various forms of peptic ulceration have been traced in some detail. It will be seen that these changes are complex, and that if we are to accept the proposition that peptic ulcer is one single clinical entity, the result of the operation of one set of aetiological factors, then it is difficult if not impossible to see how these changes could have taken place. On this historical evidence alone, even if on no other, a clear-cut distinction may be made between gastric ulcer and duodenal ulcer as separate diseases with different mortality trends. A similar distinction must be made between the chronic type of ulcer, whether sited in the stomach or the duodenum, and the acute variety. In the past the many features which these conditions possess in common have tended to obscure their essential differences and therefore led to some confusion of thought in the study of their causation. It cannot be gainsaid that all these diseases are probably related to one another, but that is not to say that they are different manifestations of the same disease process. It is suggested that such confusion and difficulty will inevitably arise in the study of these diseases unless they be considered individually until further knowledge permits of evaluation of the features they have in common. For the present it must be stressed that the history and evolution of gastric ulceration in its various forms are so very different from those of duodenal ulceration as to stamp the two conditions as separate entities.

While it cannot be denied that constitutional factors may play an important part in the pathogenesis of peptic ulceration in its various forms it is difficult to believe that fluctuations in such factors alone could be responsible for the many changes which have occurred, and these must therefore be attributed to changing environmental influences. In view of the convincing evidence of gross increase in the prevalence of gastric and duodenal ulceration the view that they are concomitants of life under modern conditions is to a large extent substantiated.

### Summary

Alterations in the incidence, age-and-sex distribution, and clinical features of gastric and duodenal ulcer are surveyed over a period of years.

In particular the changes which have occurred during the present century are examined on the basis of clinical surveys, the Registrar-General's returns, and post-mortem statistics.

It seems probable that gastric ulceration was uncommon until the beginning of the nineteenth century, and there is little evidence to suggest that duodenal ulceration was other than a rare disease until about the beginning of the present century.

Since that time there is evidence of a considerable increase in the incidence of duodenal and gastric ulcer in males. Although gastric ulcer in females has become very much rarer, investigations point to an increase in the frequency of duodenal ulcer.

The increased mortality from gastric and duodenal ulcer in males and from duodenal ulcer in females affects principally those in the later age groups, and the ageing nature of the population therefore results in an increase in total mortality which is thus more apparent than real. But even in the younger age groups mortality has either risen or remained steady, except that the mortality from gastric ulcer in young females has shrunk to negligible proportions.

Peptic ulceration is a disease which causes considerable morbidity in relation to its mortality rate. The mortality from gastric ulcer apparently exceeds that from duodenal ulcer quite apart from any deaths which may result from neoplastic change in a gastric ulcer.

Although little change can be detected in the nature of duodenal ulceration it is clear that the pattern of gastric ulceration has altered profoundly during the last 100 years.

The various forms of peptic ulceration, gastric and duodenal, acute and chronic, can from the aetiological point of view be regarded as quite separate, although they are almost certainly related conditions.

The cause of these changes, and accordingly the causation of the diseases themselves, are to be sought in environmental circumstances rather than in constitutional factors.

There is considerable support for the view that the evolution of gastric and more particularly, duodenal ulceration has paralleled the development of the highly developed civilized state of to-day.

I am indebted to Dr J F Ackroyd, Dr T C Hunt, and Professor G W Pickering for invaluable criticism and advice in the preparation of this paper.

## SOME PROBLEMS OF CAUSALGIC PAIN A CLINICAL AND EXPERIMENTAL STUDY\*

BY

JOHN A W BINGHAM, MCh, F.R.C.S

Honorary Assistant Surgeon Belfast Hospital for Sick Children  
 Formerly Surgical Specialist India Command

Ever since Weir Mitchell and his colleagues at the time of the American Civil War drew attention to the occasional occurrence of persistent pain and tenderness following nerve injuries and amputations (Mitchell, Morehouse, and Keen, 1864, Mitchell, 1872) these conditions have presented many intriguing problems. There have, however, during recent years been some advances in our knowledge of these distressing cases.

Lewis (1937) found that in some subjects cutaneous tenderness could be produced through nervous channels—for example, by stimulating a cutaneous nerve with a weak faradic current. As a result of his investigations he concluded that such hyperalgesia was due to nerve impulses leading to the liberation of a pain-producing chemical substance from cellular elements in the skin, and that the nerves concerned were not sympathetic nerves or ordinary sensory nerves, but special nerves belonging to the posterior root system. These nerves he named nocifensor nerves and the hyperalgesia they produced nocifensor hyperalgesia. It seemed to Lewis, and has seemed to many others since that this experimental hyperalgesia must in some way be related to hyperalgesia following nerve injuries, though apparently at variance were Lewis's finding that experimental nocifensor hyperalgesia could be produced after the degeneration of sympathetic nerves to the skin following sympathetic ganglionectomy and the relief of causalgic pain and hyperalgesia that is often achieved by sympathectomy.

Homans (1940), among others, has drawn attention to cases of nerve injuries in which hyperalgesia develops without spontaneous pain or at least without burning pain. He suggested that the difference between these cases and case of classical causalgia with burning pain was only one of degree, and to describe them he used the term "minor

\*A paper based on part of a thesis for the degree of Master of Surgery, Queen's University, Belfast, 1946.

causalgia." It might, however, be preferable for some such term as "traumatic neuralgia" to be used to describe the whole group of cases, whatever the degree of severity, and for the term "causalgia" to be confined to those severe cases of which burning pain is a feature, or to be used, as it was originally by Weir Mitchell (1872), to describe only the symptom of burning pain.

Riddoch (1941) remarked on the similarity between phantom pain following amputation and causalgic pain following peripheral nerve injuries. As after peripheral nerve injuries, so after amputations all gradations of pain occur. The hyperalgesia that develops in the stumps of many patients with post-amputation pain is, moreover, similar in character to hyperalgesia in cases of causalgia. And further, as pointed out by Leriche (1939), Livingston (1943), and White (1944), some cases of post-amputation pain may, like some cases of causalgic pain after nerve injuries, be relieved by sympathectomy. My personal experience has been that sympathectomy produces satisfactory relief of pain in both conditions in about 60% of cases. Pain after amputation therefore might well be called amputation causalgia.

Between October, 1944, and April, 1946, there came under my care at No. 7 Indian Base General Hospital 25 patients with amputations who had persistent pain and tenderness of some severity—in 18 of these phantom pain was the chief complaint—and 14 patients with causalgic pain following peripheral nerve injuries. A number of clinical experiments were carried out with the object of throwing further light on some of the problems connected with these cases.

### 1 Mechanism of Production of Cutaneous Hyperalgesia

In order to determine whether there was any relation between the experimental hyperalgesia described by Lewis and the hyperalgesia that develops in some cases of amputation and peripheral nerve injury, attempts were made in a number of patients to produce experimental hyperalgesia by stimulating a cutaneous nerve, most often the lateral cutaneous nerve of the forearm or the internal saphenous nerve below the knee. In 11 patients with moderate or severe pain following amputation or peripheral nerve injury hyperalgesia was readily produced in this way, whereas in eight patients with amputations or nerve injuries who did not have pain or tenderness and in four who had mild causalgic states with only slight pain or tenderness similar attempts to produce hyperalgesia failed. This finding strongly supports the view that hyperalgesia in these conditions is produced through the same nervous channels as hyperalgesia obtained by faradic stimulation.

### 2 Reasons for the Relief of Pain and Tenderness by Sympathectomy

Among the many views that have been advanced in an effort to explain how sympathectomy relieves causalgic pain and tenderness one which has occasionally been put forward, but which has usually been dismissed immediately by those who have considered it, is that sympathectomy relieves pain in some of these cases by interrupting a pain pathway from the site of nerve injury and from hyperalgesic skin.

The possibility that this view was correct first occurred to me on observing the rapidity of the relief obtained by blocking the sympathetic chain with procaine in many of these cases. I noticed that when a sympathetic procaine block relieved pain and tenderness it almost invariably did so immediately, taking no longer than the few seconds required for the procaine to produce a nerve block, and often occurring before there was any noticeable vascular

change in the limb. Lewis (1937) found that hyperalgesia produced by faradic stimulation of a cutaneous nerve persisted for many hours after nerve stimulation had ceased, but that if the nerve was first blocked with procaine and then stimulated proximal to the block hyperalgesia did not develop later when the effect of the procaine had worn off. He thus demonstrated that the nerve impulses producing hyperalgesia were transmitted only during the period of nerve stimulation and not subsequently, and that the persistence of hyperalgesia for many hours was due to the persistence of a relatively stable state in the skin, which for its maintenance "does not require a continuous flow of nerve impulses from the original source of disturbance" (Lewis, 1942). Therefore, if the effect of sympathetic denervation was merely to cause a cessation of nerve impulses to the skin, hyperalgesia would be expected to persist for several hours. The most likely explanation for the extremely rapid relief of tenderness would seem to be that when interruption of the sympathetic chain relieves pain and tenderness it does so by interrupting the sensory pathway.

In support of this view, I have elsewhere (Bingham, 1947) recorded an observation I made when excising the superior cervical sympathetic ganglion under local analgesia in a case of causalgia involving the trigeminal nerve. A number of experimental observations have been made which provide further evidence in its support.

In nine patients with causalgic pain and tenderness following peripheral nerve injury or amputation an area of experimental hyperalgesia was produced in a part of the affected limb not previously tender and a sympathetic procaine block was then carried out. For the upper limb the procaine injection was most often made beneath the second rib, and for the lower limb at the level of the second lumbar vertebra. At these levels it is unlikely that the procaine could affect the roots of the brachial plexus or of the sciatic nerve. Certainly in no case was there any evidence that these nerve roots had been affected, and in cases in which an operative sympathectomy was subsequently performed the effect of the operation on the patients' pain and tenderness was similar to that achieved by the procaine injection. In three of these nine patients sympathetic block—seen to be effective by the development of hyperaemia and increased warmth in the limb and by the cessation of sweating—did not relieve the pain and tenderness from which they had been suffering, and in these patients the experimental hyperalgesia was also not relieved. In the remaining six patients sympathetic block relieved the pain and tenderness from which they had been suffering, and also relieved simultaneously, usually within a minute of the injection, the cutaneous hyperalgesia produced experimentally. For the reason given above this rapid relief suggests that the sensory pathway had been interrupted.

A much more conclusive observation, however, was made in these six cases. After a few hours, when the effect of the procaine had worn off and the patients' original pain and tenderness had returned, the experimentally produced hyperalgesia was also found to have returned. The return of the original pain and tenderness is of no particular significance, for the conditions responsible for the original nerve irritation and therefore for the transmission to skin of the nerve impulses producing the original hyperalgesia were still present. But the return of the hyperalgesia produced by faradic stimulation cannot be explained in this way. From Lewis's demonstration that such hyperalgesia is brought about by nerve impulses transmitted to skin only during the period of nerve stimulation it follows that its return after the effect of the sympathetic block had worn off cannot have been due to further impulses then reaching the skin. The hyperalgesic state produced at the time

the nerve was stimulated must have remained unchanged, and the temporary relief of tenderness can have been due only to temporary interruption of the sensory pathway. Thus the view that in some cases, but not in all, sympathetic block or sympathetic ganglionectomy interrupts the sensory pathway from hyperalgesic skin is seen to receive definite experimental confirmation.

As already noted, Lewis found that hyperalgesia could be produced in some subjects after sympathectomy, and he naturally concluded that neither the efferent nor the afferent pathway was by way of the sympathetic chain. This finding of Lewis's has, however, been brought into accord with those described above by demonstrating that while hyperalgesia may be produced after sympathectomy in some individuals, as was found by Lewis, this cannot be done in all those individuals in whom experimental hyperalgesia may be produced before sympathectomy. I have found in two patients whose causalgic pain and tenderness had been relieved by sympathectomy that it was no longer possible, as it had been before operation, to produce an area of hyperalgesia on the affected limb.\* On the other hand, in one case of post-amputation pain and tenderness in which sympathectomy had been performed without relieving the condition it was still possible after operation to produce readily an area of hyperalgesia on the stump.

Whilst these experiments indicate that sympathectomy in some cases interrupts the pathway for causalgic pain it does not necessarily follow that there are not occasional cases in which sympathectomy is of benefit for other reasons. I have had one case of causalgia—a case following a vascular injury—in which sympathetic block relieved pain and tenderness, not immediately, but after several hours. In this particular case sympathetic block clearly did not interrupt the pain pathway, and benefit was probably due to relief of vasospasm and improvement in blood supply to ischaemic nerves.

### 3 Reason for Failure of Sympathectomy in some Cases

The experience of most observers has been that in some cases of undoubted causalgia sympathectomy fails. My personal experience has been that in about 40% of cases interrupting the sympathetic chain, though it causes such associated symptoms as cyanosis and increased sweating to clear up, produces little or no relief of pain or tenderness. There would appear to be two possible reasons for the failure of sympathectomy in these cases.

1 Pain may arise centrally, in the spinal cord or in higher centres. But this would fail to explain the persistence of skin tenderness, and it is almost always found that when sympathectomy or sympathetic block fails to relieve spontaneous pain it fails also to relieve cutaneous tenderness.

2 Pain may still arise in the periphery but may follow some other pathway. To investigate this possibility attempts were made in 10 patients with causalgic pain and tenderness, on whom sympathectomy or sympathetic blocks had proved ineffective and on whom no operations, except in some cases operations on peripheral nerves or amputation stumps, had been performed, to relieve their pain and tenderness by procaine block of individual peripheral nerve trunks, by brachial plexus block, or by low spinal analgesia. In all cases pain was relieved, and therefore, as suggested, in these cases pain must have arisen in the periphery, but must have followed some pathway other than the sympathetic chain. The only alternative pathway that seems at all likely is by the posterior roots of the nerves that had been injured.

\*At the time these patients were tested after operation an area of hyperalgesia was easily produced at a corresponding point on the opposite limb, thus showing that, except for the part affected by the sympathectomy, the proneness of the patients to develop hyperalgesia had remained unaltered.

### 4 Reason for the Frequent Failure of Posterior Root Section and Chordotomy

There is no difficulty in explaining why posterior root section should fail to relieve pain and tenderness when the pain pathway is by the sympathetic chain. But apparently, even in those cases in which interruption of the sympathetic chain is without effect, posterior root section, though it may relieve tenderness, does not often succeed in relieving pain. And while section of the contralateral spino-thalamic tract is sometimes successful (Taylor, 1938, White, 1944), this operation also may fail (Ministry of Pensions, 1939, Bailey and Moersch, 1941). The difficulty of reconciling the failure of these operations with the view that in these cases pain from the periphery was reaching the cord by way of the posterior roots of the injured nerve would, however, seem to be overcome by observations I made on two cases.

The first of these cases was that of a patient with phantom pain and tenderness following an upper-limb amputation who was treated by contralateral-tract section at the level of the second cervical segment after an operation on the stump and sympathectomy had proved unsuccessful. There was complete freedom from pain and tenderness for several days. Pain then gradually returned, and in a few weeks was very much as it had been before the operation. Tenderness, however, remained very considerably relieved.

In the other case that of a patient with severe phantom pain and tenderness following a lower-limb amputation, chordotomy at the level of the sixth thoracic segment was performed after lumbar sympathetic blocks had been found to give no relief. Pain and tenderness were completely relieved for a day or two. Some pain then returned, though this remained less severe than before. Tenderness was completely relieved.

The satisfactory relief of stump tenderness by chordotomy in both these cases would seem to indicate that the failure to relieve pain was not the result of failure to interrupt the sensory pathway from the periphery. Moreover, careful examination of sensation in both cases some time after operation showed that the return of pain could scarcely have been due to the levels of cord section not being high enough, for it was found in both that pain sense began to diminish one dermatome below the level of section and appeared to be completely absent a few dermatomes below that level. Therefore tract section at C2 level in the first case should have been at a level high enough to produce marked relief of pain in the phantom hand, and certainly in the second case section at T6 level should have been sufficiently high.

It is necessary, therefore, to look for some other explanation. Some months after operation attempts were made to relieve pain in the first case by means of brachial plexus blocks on three occasions and in the second case by means of spinal analgesia to T11 segment. In neither case was any relief of pain produced.

Two possible reasons for these findings require to be considered. (1) In these two cases spontaneous pain might have arisen centrally before the performance of any operations. This must be regarded as extremely unlikely, for it would have been an extraordinary coincidence for chordotomy to have been carried out on the only two such patients I encountered. (2) Following these operations a new focus of pain production might have developed in the cord or in higher centres. The relief of pain that occurred in these cases for a few days after chordotomy lends support to this view, for it seems likely that this temporary relief was due to interruption of the pain pathway from the periphery and the return of pain to the development of a new central focus. If the effect of spinal analgesia or brachial plexus block had been observed in these cases before the perform-

ance of chordotomy more conclusive evidence might have been obtained, but this unfortunately had not been done

However, in the case of the patient with the upper-limb amputation who was treated by chordotomy in the upper cervical region the possibility that the cord section had given rise to a new focus of pain production receives support from a further observation. From a few weeks after the operation this patient complained of painful sensations in the leg on the side of the amputation as well as in the phantom arm, even though the leg was completely analgesic. Sometimes there was only an itching or pricking sensation in the leg, but at other times there was burning pain and a pulling pain deep in the foot. The patient mentioned these pains without being questioned, and there would seem to be no doubt about their having been genuine. Pain in both the arm and the leg is what would be expected if pain resulted from section of the spino-thalamic tract in the upper cervical region, and no reason can be thought of for pain in the leg to have arisen as a functional condition. Riddoch (1941), moreover, has drawn attention to the painful phantom-limb sensations that occasionally develop in paraplegic patients who have suffered complete division of the spinal cord. These painful sensations would appear to be exactly similar in origin to the pain experienced by this patient after chordotomy.

It is possible to see how posterior root section also might lead to a central focus of pain production, for pain fibres in posterior roots, cut off by the root section from their cells of origin in posterior root ganglia, would undergo degeneration, and this might well cause changes around posterior horn cells that would in some individuals give rise to pain.

Thus when either chordotomy or posterior root section fails to relieve causalgic pain it is not necessary to conclude that pain was functional or that it had, before the performance of these operations, arisen centrally.

### 5 Conclusions concerning the Pain Pathway and the Nature of the Nerve Fibres

It is unlikely that the nerve fibres that convey pain from the site of nerve injury and from hyperalgesic skin sometimes reach the cord entirely by way of the posterior roots of the affected peripheral nerve and in other cases entirely by way of the sympathetic chain, thus passing to cord segments in the thoracic region. The most acceptable explanation of the findings that have been described is probably that in all cases these nerve fibres follow to some extent both pathways, the actual proportion following each pathway varying in different individuals. This double pathway (shown diagrammatically in the accompanying illustration) may exist even when complete relief follows blocking of one pathway alone, for any considerable reduction in the

Diagram illustrating the double pathway followed by the nerve fibres that convey causalgic pain between an injured peripheral nerve and the spinal cord. A = Nerve fibre that conveys causalgic pain by way of the posterior root of the injured nerve. B = Nerve fibre that conveys causalgic pain by way of the sympathetic chain and by the posterior root of a thoracic spinal nerve.

number of pain impulses may reduce the number reaching consciousness below that necessary to give rise to a sensation of pain.

These nerves cannot be regarded as belonging to the physiological sympathetic system, if only for the reason

that they do not always follow this pathway. Presumably, like other sensory nerves, including visceral afferents running in the sympathetic chain, they have their cell station in posterior root ganglia. However, most recent investigations have failed to show any alteration in sensory acuity after sympathectomy (Lewis, 1942, White and Smithwick, 1942), and in a few patients whose sensation I examined after their causalgic pain had been relieved by sympathectomy it was not possible to detect any diminution as compared with the opposite normal limb in either the intensity or the duration of pain sensation. Threadgill (1947) has, it is true, obtained evidence from animal experiments which indicates that painful stimuli may be appreciated by impulses transmitted centrally over the sympathetic chain. Nevertheless, if the nerves that form the sensory pathway for causalgic pain and tenderness play any part in normal sensory appreciation it can be only a very subsidiary and unimportant part, and it would seem desirable to distinguish them from other nerves belonging to the posterior root system. This may be done by using the term nocifensor nerves, already suggested by Lewis for the nerves concerned with the production of hyperalgesia.

We have seen that pain may result from cord section when this is carried out in patients with causalgic pain. Chordotomy for other conditions apparently yields better results, and it would therefore appear that it is those individuals who develop pain after injury to peripheral nerves who are liable to develop pain following injury to the spino-thalamic tract. Thus the nocifensor nerves responsible for the development of causalgic pain appear to be associated with neurones in the cord that also cause persistent pain when injured, and it seems a reasonable assumption that these neurones are special central connexions of the peripheral nocifensor nerves.

### 6 Reason for Causalgic States Developing in Certain Patients

It is necessary to explain why, of two patients with an apparently equally mild or equally severe nerve lesion, one may have causalgia and the other not, and why, of two patients with an apparently equally perfect or equally imperfect amputation stump, one may have a painful phantom and a painful hyperalgesic stump and the other not. It is also necessary to explain how pain may persist after division of nerves well above the site of the original injury. The conclusion would seem to be inevitable that these conditions are not due to any peculiarity in the nature of the lesion but to an abnormality in the nerves of individual patients that may be said to render them "causalgia-prone". That individual variation in nocifensor nerves is related to the development of causalgic pain is shown by hyperalgesia from faradic stimulation being readily produced only in those patients with amputations or nerve injuries who have a marked degree of pain.

This does not mean that such factors as the type of trauma or the development of infection are never of any importance. But there would not seem to be any doubt that a more important factor than the nature of the lesion is an abnormality in the nerves of the patient concerned, and that this takes the form of an unusually well developed nocifensor system.

### Summary and Conclusions

From clinical observations and from the findings in a number of clinical experiments the following conclusions have been arrived at concerning the development of causalgic pain and tenderness.

1 The nerve fibres concerned in the production of hyperalgesia in causalgic states and the nerve fibres conveying pain

from the site of nerve injury and from hyperalgesic skin are special nerves—the nocifensor nerves first described by Lewis

2 These nerves travel in varying degree by two alternative pathways between an injured peripheral nerve and the spinal cord. One pathway is by way of the sympathetic chain to thoracic cord segments, the other by way of the posterior roots of the injured nerve

3 The site of origin of causalgic pain following peripheral nerve injury or amputation is before the performance of such operations as chordotomy or posterior root section, in the periphery

4 The reason for pain persisting or returning after chordotomy, or after section of the posterior roots of an injured nerve, when these form the principal pain pathway, is the development of a central focus of pain production

5 The chief factor in determining whether or not pain develops after injuries to peripheral nerves or after amputations is individual variation in nocifensor nerves rather than the nature of the nerve lesion

My thanks are due to Mr Grant Massie, late Brigadier, A M C, and Consulting Surgeon India Command, for providing me with the opportunity of carrying out this work, and for his interest and encouragement. I am also indebted to my former colleagues, Lieutenant-Colonel H R Pasricha, I M S, and Major T Denness, I M S, for allowing me to examine and investigate patients under their care

## A FATAL CASE OF MYELITIS AFTER ANTIRABIC VACCINE

BY

I ANSELL, MD, MRCP

Late Major R A M C, Medical Specialist

This case is recorded because of the rarity of the accident occurring with antirabic vaccine, and because of the renewed interest in its pathogenesis following work by Kabat *et al* (1947) in the artificial production of similar lesions in monkeys

### Case Record

The patient, a white soldier aged 26 serving in India, was in perfect health and physical development a few days before his admission to hospital on July 9 1946, when he first complained of fever and pains in his limbs. He had been bitten by a healthy puppy 14 days previously, and had received 12 antirabic injections, starting two days after the incident. The dog was said to be still healthy and the course was thereupon stopped

On examination his temperature was 101° F (38.3° C), pulse 88, and respirations 18. He was inclined to be drowsy, his tongue was furred, and there were several red areas on the front of his abdomen at the sites where the injections had been given. With the exception of a few rhonchi audible in the chest and slight enlargement of the axillary and inguinal lymph glands, nothing abnormal was observed. Routine blood slides

examined four-hourly were negative for malaria parasites. He was treated symptomatically with a mixture containing acetylsalicylic acid, 3½ gr (0.23 g), phenacetin, 2½ gr (0.16 g), and caffeine, ½ gr (32 mg), six-hourly

On 10 July he appeared to be more toxic. His eyes were congested and his face flushed, his temperature was 104.6° F (40.3° C). There were still no physical signs beyond those of mild bronchitis and slight glandular enlargement. Repeated blood slides were still negative for malaria parasites, and a white cell count was 12,800 per c mm (polymorphs 79%, lymphocytes 18%, monocytes 2%, and eosinophils 1%). Routine blood cultures and agglutinations were taken, the results being later reported as typhoid and paratyphoid A-O, 1/40, *Proteus* OX 2 and OX 19, 1/25, *Proteus* OX K, 1/50, blood culture sterile. In view of the local endemicity of malaria, a course of quinine sulphate, 10 gr (0.65 g) thrice daily, was started. Later that evening it was noticed that he had not passed urine, and it was necessary to catheterize him. At this time he began to experience bouts of hiccupping and vomiting.

On July 11 the bronchitic signs had increased. Urinary retention persisted and failed to respond to 1 ml of acetylcholine intramuscularly, so that catheterization was necessary. Next day he started to complain of inability to move his legs. The hiccup had become more distressing, but he was still quite clear mentally, and his temperature had fallen to 99° F (37.2° C). Clinical examination at this stage revealed no abnormality of the cranial nerves, there being no laryngeal spasm or dysphagia. The upper limbs were normal, but there was a flaccid paralysis of the lower limbs, with absent knee-jerks, depressed ankle jerks, and flexor plantar responses. There were no sensory changes. The differential diagnoses now considered included paralytic rabies, the neuromuscular effects of antirabic vaccine, and poliomyelitis. The first diagnosis was unlikely, as the dog was still healthy, leaving the effects of the vaccine and poliomyelitis as possibilities. When seen later that morning the patient was cyanosed, dyspnoeic, and troubled by ceaseless hiccup. The paralysis was now ascending, involving his lower abdominal musculature and threatening to involve his respiratory muscles. In view of this possibility he was transferred to our hospital at Barrackpore, where there was an iron lung. During the journey by ambulance his respiration became distressed, so that he required oxygen and artificial respiration from time to time.

When seen on arrival he was still conscious, but was very distressed. A rapid examination showed the cranial nerves to be normal, there being neither laryngeal spasm nor dysphagia, and no neck rigidity. The upper limbs appeared to be normal. The lower intercostal and abdominal muscles were paralysed and the superficial reflexes were absent, but the diaphragm was still functioning. There was a flaccid paralysis of the lower limbs with absent knee- and ankle-jerks, the plantar responses being indeterminate. No gross sensory disturbances could be demonstrated. Examination of the chest revealed diffuse rhonchi with moist sounds audible chiefly at the bases. There were angry red indurated areas on the abdomen at the sites of the previous inoculations. Neither the liver nor the spleen was enlarged, but the bladder was distended. It was decided to catheterize him and leave him with an indwelling catheter. A course of penicillin was begun (50,000 units four-hourly, intramuscularly) to combat the secondary respiratory infection. The patient was then put into an electrically driven iron lung of the Nuffield pattern. Intermittent oxygen was administered as he appeared to be having difficulty in accommodating himself to the iron lung. At times he lapsed into delirium, shouting out orders to imaginary persons as though involved in a fight. He was then given phenobarbitone, 1 gr (65 mg), and a bismuth mixture, which quieted him and relieved his hiccup. Later in the evening the paralysis spread to his shoulder and upper-limb musculature, but he could still move his fingers. During the night his condition continued to deteriorate, and by morning the paralysis had involved the muscles of deglutition, necessitating nasal feeding. Later in the morning (July 13) he became unconscious, his general condition became much weaker, and he died five hours later without recovering consciousness. A lumbar puncture performed within an hour after death yielded a clear cerebrospinal fluid with a protein of 100 mg per 100 ml and 110 cells per c mm (lymphocytes 64%, large mononuclears 36%).

**Necropsy Report** (Capt I P V Leggett, I A M C)—The brain appeared congested on its outer surface, but on section there was no gross macroscopic abnormality. The coverings of the cord were congested, the pial blood vessels being very prominent. On section the cord was oedematous, with mushrooming of its edges, but there were no visible haemorrhages in its substance. With the exception of slight prominence of the mesenteric lymph glands and terminal hypostatic pneumonia, no other abnormality was found. The brain and cord were removed and fixed in formalin before dispatch to Major L. Krainer, at the C M P L, Poona. His report was as follows: "Spinal-cord sections stained by H and E show numerous perivascular foci of demyelination situated in the white matter without any systematic arrangement, all the foci are new and show cellular proliferation in addition to destruction of axis cylinders and myelin sheaths. There is extensive perivascular round-cell infiltration in the substance of the cord, and there are a few round cells in the meninges. Sections of the brain-stem show the same process with lesser intensity extending up to the pons. No pathological changes were detected in the cortex cerebri and cerebelli. Diagnosis: acute disseminated myelitis extending into the brain-stem."

### Discussion

This case illustrates several interesting features. On the history a diagnosis of rabies is unlikely. The probable diagnosis is a polyneuritis or myelitis due to the antirabic vaccine, the former being less likely in view of the absence of sensory changes. This paralytic accident being very rare, an alternative cause for the ascending myelitis could be acute anterior poliomyelitis, particularly as the latter is endemic in this part of India and is usually very virulent in British troops. Clinically these two conditions are indistinguishable.

The incidence of neuromuscular accidents following antirabic vaccine has been given by Greenwood (1945-6) as being 1 in 8,517 cases (0.012%) treated with killed phenol vaccine, and 1 in 5,814 cases (0.017%) for all types of antirabic vaccine, including killed phenol type, the mortality in the two groups being 25%. The onset usually occurs 13 to 15 days (maximum period 35 days) after the first injection of the vaccine, and may take one of four forms (Van Rooyen and Rhodes, 1940): (1) An acute ascending paralysis of the Landry type. The mortality from this is in the region of 30%, the remainder recovering completely. (2) A dorso-lumbar transverse myelitis, which is usually localized, affecting the lower limbs, bladder, and rectum. This complication is more common than the Landry type and has a mortality of less than 5%. A non-fatal case of this type was described by Imrie (1944). (3) A mononeuritis or multiple neuritis involving the cranial or peripheral nerves, and rarely the optic nerve, causing papilloedema as in the case described by Koenigsfeld (1945). (4) A meningo-encephalomyelitis syndrome described by Gordon and cited by Remlinger (1937). A case conforming to this type was described by Bussell (1946).

The various theories advanced to explain these accidents include causation by a virus, toxins, or allergy.

**The Virus Theory**—These accidents were attributed to the "street" virus modified by antirabic vaccine until cases occurred in persons not bitten by rabid animals, when the virus *fixe* was suspected of pathogenicity. Bassoe and Grinker (1930) were impressed by the similarity of their cases of encephalomyelitis after antirabic vaccine to those due to vaccinia and infectious fevers, and considered that an attenuated virus was transmitted by the vaccine. This view was held by Remlinger (1937) when vaccines containing the live virus were used. The neuritic group of accidents resemble the neurological complications following serum and other types of vaccine therapy described by Hughes (1944), in the aetiology of which a virus is suspected.

**The Toxin Theory**—There is no convincing evidence that the vaccine contains rabies toxin, nor has the existence of this

endotoxin ever been proved. Stuart and Krikorian (1928) produced paralytic lesions in rabbits by repeated inoculations of normal heterologous nerve tissue. They believed that the basic nerve substance of all antirabic vaccines contained a cytotoxin modified by physical and chemical agencies which could produce neuromuscular accidents in susceptible persons.

**The Allergic Theory**—Inoculating normal heterologous nerve substance into monkeys, Ferraro and Jervis (1940) produced disseminated neurological lesions with a pathological picture of perivascular infiltration and demyelination. They postulated that the lipoid of the white matter functioned as a haptene, being actuated by the presence of protein. Similar effects, accelerated by the addition of adjuvants to brain-tissue inoculations, were produced by Kabat *et al* (1947), who believed the antigen to be bound up with the myelin portion of the tissue. In a series of 16 patients developing neuromuscular accidents, Horack (1939) reported a family or personal history of allergy in 87.5%, compared with 33.3% in controls. He suggested that those with a history of allergy should be tested for sensitivity to the vaccine. It was also suggested that the appearance of severe local reactions during treatment might indicate the simultaneous development of sensitivity in the central nervous system of some patients. For each of these types of sensitivity Horack described a method of desensitization.

In the above case killed carbolized vaccine was given, and skin sensitivity in the form of prominent reactions at the sites of inoculation was manifested. According to his friends the patient had never been ill before, but unfortunately the family history with regard to allergy could not be ascertained. The pathological findings of well-marked perivascular infiltration and demyelination in this case are similar to those seen in Kabat's experimental lesions, although the latter were chiefly distributed in the brain. These findings differ from those of Stuart and Krikorian, in which mesodermal reactions were absent, but are similar to those of Bassoe and Grinker and to those of Bussell, with the exception of the intense meningeal reaction and haemorrhages in the latter's case. The balance of evidence would seem to be in favour of acquired anaphylaxis as the causation in the above case. It is probable, however, as suggested by Remlinger, that there is no single cause which will account for all types of neuromuscular accidents.

### Conclusions

Antirabic treatment should be given only when the correct indications are present. A healthy dog should be kept under observation for the usual ten days before treatment is begun, except, possibly, in cases of severe bites on the face.

A family or personal history of allergy indicates the need for preliminary skin tests for sensitivity, and if excessive local reactions occur during treatment the desirability of desensitization should be considered. If the neuromuscular complications have already made their appearance, then in view of the serious prognosis, especially in the Landry type, it would be worth while to try out the effect of antihistamine drugs on the basis of the allergic theory. At the same time the effect of these drugs on the skin reactions should be observed.

It is essential that an iron lung should be available in case of respiratory failure, preferably in an air-conditioned room if in the Tropics. For the purpose of minimizing respiratory complications a good suction apparatus is a great asset in clearing the secretions that accumulate in the pharynx of these patients.

The usual precautions during antirabic treatment—avoidance of unnecessary exertion and of alcohol, and provision of adequate rest—should be strictly enforced.

Post-mortem examination, with removal of the cord and brain, should be carried out in all obscure cases of myelitis as soon as possible after death so that further information may be obtained and an exact diagnosis made. A portion of

the brain and cord should be preserved in glycerol-saline or, better still, by refrigeration for virus studies

Methods by which the amount of myelin tissue in these vaccines could be reduced to a minimum should be sought and perfected

### Summary

A fatal case of acute disseminated myelitis following anti-rabic treatment is described, together with the post-mortem findings

The differential diagnosis and the aetiology are discussed

Suggestions are made to reduce the incidence of these accidents in the future

I wish to thank the DGMS, War Office, for permission to publish this article, Captain R D Eagland, R A M C, for his assistance in treating this case, and Dr A R D Adams, of the Liverpool School of Tropical Medicine, for valuable criticism

## Medical Memoranda

### Convulsions under Trilene Anaesthesia

Convulsions under trilene anaesthesia have been reported by Culbert (1942) and by Garland (1942), but in view of the rarity of the condition and because of the increasing use of this drug publication of the following case report is warranted

#### CASE REPORT

A soldier aged 20 was transferred from the V D wing to the minor surgical ward with chronic balanitis and was brought to the operating theatre on Aug 11, 1947, for circumcision. His general condition was good, and 75 minutes before the operation he was given 1/3 gr (22 mg) of 'omnopon' and 1/150 gr (0.43 mg) of scopalamine. Anaesthesia was induced, using the standard Army Boyle machine, with nitrous oxide and oxygen. Trilene was added to the mixture and the patient maintained in stage 3, plane II anaesthesia.

Midway through the operation convulsive movements of the arms began, the legs became similarly involved, and this developed into generalized convulsions. The operation was stopped, no further inbalation anaesthetic was given, and oxygen was administered. With some difficulty an intravenous injection of thiopentone was made, and the convulsions were controlled after the patient had received 0.2 g. Apnoea resulted, but no treatment was required for this, since respiration restarted almost at once.

As the patient's general condition was fair, the blood pressure being 110/70 and the pulse rate within normal limits, the operation was completed under nitrous-oxide-oxygen anaesthesia. The patient's pre-operative temperature was normal, and during the operation the theatre temperature was 24° C. Atropine was not given. The Trendelenburg position was not used. Except for some slight anoxia during the induction stage, oxygenation appeared adequate throughout. Respiration showed no evidence of carbon dioxide imbalance.

Post-operative recovery was normal, and investigations showed blood urea, 20 mg per 100 ml, blood sugar, 90 mg per 100 ml, serum calcium, 11.5 mg per 100 ml, Kahn test negative. Facilities for an electro-encephalogram were not available.

#### COMMENT

This was not a case of tremor or spasm but of quite definite convulsions. These started in the limbs and not in the muscles of the eye and face as with deep ether convulsions.

Circumcision in the young adult requires moderately deep anaesthesia, and that produced in this case was adequate, although trilene was not pushed to the extent of producing tachypnoea.

The only factors mentioned by Minnitt and Gillies (1944) in the production of deep ether convulsions present in this case were a young adult patient and a septic condition—i.e., balanitis—but this was not in the least severe.

### A Case of Strangulated Epigastric Hernia

Strangulated epigastric hernia is an unusual emergency. The literature from 1927 to 1946 contains only three cases of this condition (Chevereaux, 1929, Delannoy, 1933, Ballati, 1934) and two cases of incarcerated epigastric hernia (Zhman, 1934, Popper, 1936). The case reported below is of interest because of its rarity and the added difficulty in diagnosis owing to associated bilateral irreducible inguinal herniae.

#### CASE REPORT

A man aged 65 was admitted to hospital with a history of severe vomiting for one day. He was of very low general intelligence. Associated with this vomiting there was marked epigastric pain with severe prostration. "Swellings" had been present in both groins and in the epigastrium for as long as he could remember. While in the admission room he vomited about 1 pint (570 ml) of dark brown fluid.

Examination revealed considerable dehydration and a furred and dry tongue. The temperature was subnormal and the pulse just perceptible. Bilateral irreducible inguinal herniae were present. Neither of these herniae was tender, and they had not lost an impulse on coughing. In the epigastrium, midway between the umbilicus and xiphisternum, was a tense and tender swelling about the size of an orange. The rapid onset of a high intestinal obstruction with severe pain and collapse associated with these physical signs pointed to the epigastric swelling as the cause of the present crisis.

The stomach contents were aspirated and a Ryle's tube left in position. Two pints (1.14 litres) of glucose saline were given intravenously. The general condition improved enough for operation to be performed. Procaine infiltration analgesia was used. A transverse incision was employed and the hernial sac exposed. This proved to contain a quantity of foul blood stained fluid and a gangrenous loop of bowel in "W" formation. A rapid resection of some 12 in (30 cm) of bowel was performed and an end to end anastomosis carried out. Repair was effected with overlap using catgut sutures. A small corrugated drain was left in the subcutaneous tissues.

Gastric aspiration was continued for two days with intravenous drip. At the end of this period the general condition was good and feeding was started. The patient had an uneventful convalescence.

#### COMMENT

Epigastric hernia is probably a congenital abnormality. Difficulty in diagnosis occurs in that severe epigastric pain with tenderness and muscular rigidity may well be mistaken for an upper abdominal inflammatory lesion or for a perforated peptic ulcer. Pancreatitis may also be suspected, particularly when the hernia is small (Maingot, 1940). Richter's hernia may occur, causing a further confusion in diagnosis. A case has been reported in which the round ligament of the liver was involved in the hernial sac (Ballati, 1934). As might be expected, incarceration of the stomach has also been reported (Zhman, 1934).

## Reviews

### CALCIFIED AORTIC VALVES

*Calcific Disease of the Aortic Valve* By Howard T Karsner, M D, and Simon Koletsky, M D (Pp 111, illustrated 30s) Philadelphia and London J B Lippincott Company

Calcifying disease of the aortic valve is such an arresting discovery at necropsy that its origin has been a matter of debate for centuries. In this monograph Karsner and Koletsky set out to determine the aetiology of the lesion. As a preliminary they have reviewed past researches and opinion. Up to the time of Monckeberg's classic paper in 1904 most writers had subscribed to the theory of degeneration, but subsequently his view that many of these lesions were consequences of inflammation became prevalent. Analysing the data from their 200 hearts with aortic lesions the authors broadly divided them into a group showing gross rheumatic lesions in addition to the disease of the aortic valve (91 cases) and a group in which the gross lesions were confined to the aortic valve (109 cases). Of the second group 80 showed clear-cut microscopical evidence of rheumatic disease. A further study of the 29 outstanding cases left only 4 in which the evidence of past rheumatism was inconclusive. Careful analysis of their extensive pathological material failed to support the view of Monckeberg and others that the nature of the disease can be distinguished according to the site of the calcification.

The clinical data emerging from this painstaking survey are interesting and sometimes remarkable. While most clinicians might guess that calcific aortic valve disease is three times as common over the age of 50 as under that age, many would be surprised to know that diastolic murmurs were recorded in fewer than 20% of cases and absence of aortic second sound in fewer than 5%. However, this monograph is essentially based on pathology and the chapter on specific clinical considerations and the clinical data in general are less impressive than the sections on morbid anatomy and histology. Concluding with the generalization that "with only rare exceptions, calcific disease of the aortic valve is the result of rheumatic cardiac disease" the authors assign to this lesion, which has hitherto been of doubtful origin and meaning, a definite place in pathology and an undoubted significance in clinical medicine.

K. SHIRLEY SMITH

### ESSAYS IN MEDICAL HISTORY

*No Retreat from Reason and other Essays* By Alfred E. Cohn (Pp 279 \$3 50) New York: Harcourt, Brace and Company (383, Madison Avenue)

The author of these essays is a veteran cardiologist, and although only four are on primarily medical or physiological topics all are informed with that knowledge of human strength and weakness which an experienced physician who has travelled widely is sure to possess. In the reviewer's opinion Dr Cohn's lecture on the development of the Harveyan circulation is from the literary point of view his best essay. His appreciation of Harvey's greatness, which he puts in the clearest light, never leads him to depreciate the genius of Harvey's remote predecessors. "One must read Galen to appreciate the excellence of the system he instituted, its internal coherence, its consideration of all these and other matters including the change from fetal to the post-embryonic circulation." He praises Harvey as that great man might have wished to be praised.

Dr Cohn includes three biographical papers—one autobiographical, the others on Simon Flexner and the cardiologist John Wyckoff. These will appeal more to American than foreign readers, because naturally they assume knowledge a foreign reader does not possess. The most ambitious essay—on the difference between art and science in their relation to nature—contains much interesting and acute discussion of the points of view of artists and men of science, but might have been improved by condensation. On p 140 we read "No one doubts that science is concerned with the outside, with the physical world, with what is called 'objective reality'." I should think most pure mathematicians doubt it, and by

p 191 Dr Cohn seems to doubt it, for he allows that elegance, technical proficiency, and the rules of the craft do have a place of honour in science, and his general conclusions seem to be that it is very hard to draw a line between art and science, that one can hardly go further than to say that, "whereas it was in the nature of science to be general, it was in the nature of art to be individual."

Dr Cohn is a picturesque writer, sometimes perhaps too picturesque. In speaking of the famous lecture in 1616 at which, according to tradition, Harvey first announced his discovery, Dr Cohn writes "A company of great distinction was present. Although they may not have numbered above forty in all from the college, many, of the curious of the town, like Evelyn, Digby, Browne, and Pepys, may have been present." Here the word "like" is significant of much. Pepys and Evelyn were not born in 1616, Kenelm Digby was 13, and Browne (if the great Sir Thomas is intended) was 11. But these are trifles. Those who care for medical and social history will enjoy Dr Cohn's essays.

MAJOR GREENWOOD

### GYNAECOLOGICAL OPERATIONS

*Die Gynakologischen Operationen* By Heinrich Martius. Fifth edition (Pp 424, illustrated Mk 58) Stuttgart: Verlag Georg Thieme 1947

Martius's textbook of gynaecological operations has now reached its fifth edition since its first appearance in 1936. Though short, it is of excellent quality, and it is interesting that so good a book can be published in Germany at the present time. It has been translated into English and is well known in America and in India. The style is concise and anyone who has an elementary knowledge of German can read the book. Martius has based his descriptions on topographical anatomy. References to the work of gynaecologists outside Germany and Austria are scanty; this is particularly noticeable in the sections on the formation of an artificial vagina and operations for stress incontinence. The illustrations are exceptional, for they show great originality, and although many have been modified from well-known drawings almost every one reveals Martius's personality. Most are coloured, and the book compares favourably with even the best of the American publications.

The author adequately describes and illustrates the routine operations, and considers fully the anatomy of the musculature round the base of the bladder and the urethra. He describes an operation for interposing the bulbo cavernosus muscle between the urethra and the anterior vaginal wall for the treatment of stress incontinence and after the repair of a vesico-vaginal fistula. The accounts of vaginal operations are excellent, and again many of these illustrations show great originality. Very useful practical operative details can be found on almost every page. We can strongly recommend the book, and it is strange that the English translation is not widely known in this country.

### PHARMACOLOGY

*A Manual of Pharmacology and its Applications to Therapeutics and Toxicology* By Torald Sollmann M D. Seventh edition (Pp 1,132 £2 17s 6d) Philadelphia and London: W B Saunders Company 1948

This standard work, which appears at intervals of about six years, has now reached its 7th edition. It remains one of the most useful reference books on the action of drugs that we have, for the author still follows the literature with great care and assiduity and manages to fit the new information into the book. It now has a larger page and an improved lay-out. It is said that when Prof Sollmann had the Chair at Cleveland he expected the students to be closely familiar with most of the book. If that is so they must have suffered indeed, for it is essentially a work of reference rather than a textbook. There is little discussion of modern developments of the theory of drug action and it is evident that the author has in general paid more attention to work in the USA than to British work. However this complaint can usually be made against all medical books, for the vastness of the literature obliges the author to select, and it is perhaps natural that he selects the work of his countrymen.

The book nevertheless deserves high praise, and the medical world is greatly indebted to the author for its excellence. It contains in addition to pharmacological information much on the toxic effects of substances used in industry. To provide in one volume well chosen details about the multitude of substances on which experimental work has now been done is all that is possible to-day.

### BILATERAL RENAL CALCULUS

*Die Beiderseitige Nierensteinkrankheit* By Dr Bertrand Bibus (Pp 170 40 illustrations OS 60) Vienna Verlag Wilhelm Maudrich

This is the book of a surgeon whose real interest and skill are in the management of those difficult cases of bilateral renal calculus—the indications for operation, the timing of operative intervention, and the choice of which side to tackle first. In all these matters the author obviously speaks with the knowledge and wisdom of experience. He has included sections on the causation of renal calculus and the non-surgical methods of treatment, including the various so-called cures by balneo- and hydrotherapy. Although he himself has little faith in such methods he is often uncritical and unscientific in this part of the book.

Altogether there is little that can be called new or original here, and the reader finds with disappointment that he is still no nearer to learning the cause of renal calculus. This is a book which the expert urologist may like to read but which does not open up any new territory.

ROBERT PLATT

### VENEREAL DISEASES

*The Venereal Diseases. A Manual for Practitioners and Students* By James Marshall, M.D., B.S., M.R.C.S. L.R.C.P. Second edition. With additional information on the use of penicillin (Pp 369 illustrated 21s) London Macmillan and Co 1948

The second edition of this book differs from the first mainly in the addition of two chapters and further details on the use of penicillin, and by a note on Reiter's syndrome. In the introduction it is stated that two years have elapsed since the publication of the first edition yet the two editions are dated 1944 and 1948 respectively presumably a considerable period elapsed between the preparation of this edition and its publication. It can be said without hesitation that the book is practical and objective and should be of great value to the general practitioner who treats cases of V.D. and also to the venereologist starting training. The illustrations are excellent and the coloured plates beautifully reproduced. The author's views are sound and for the most part accord with modern British ideas. He is enthusiastic about the effect of penicillin in cases of gonorrhoea, but, very properly, cautious about its curative effect on syphilis. He seems to be rather sceptical whether the antibiotic is as effectual when given at longish intervals in a delaying base as when given every three hours in a watery solution, most people think there is little to choose between the therapeutic effects but the former method is much more convenient in the V.D. clinic and in private practice.

The author is hardly a literary stylist, but he generally succeeds in making his meaning clear, though the sentence (p 296) "Infectious relapse occurs in 95% of cases by the end of the third year" might be taken to mean that relapse occurred in 95% of all cases. Future editions would be improved if they included more detailed information about B.A.L. and a somewhat fuller discussion of false positive serum tests for syphilis, a subject much in the limelight to-day. Such solecisms as *magna therapia sterilisans* and *flagellae* confirm one in the belief that a study of the classics is still a necessary part of a liberal education.

T E OSMOND

Fully half of Mr J H Doggart's *Children's Eye Nursing* (Henry Kimpton 8s 6d) is devoted to a clinical exposition of the common diseases of the eye in children. This is followed by chapters on non-operative treatment, instruments and dressings, minor operations and major operations. The concluding chapter is on the care of school children. The writing is clear and the teaching orthodox. The text is profusely illustrated.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Insects of Medical Importance* By J Smart, M.A., D.Sc. and others 2nd ed (Pp 295 20s) London Trustees of the British Museum 1948

Notes and diagrams for the identification of insects

*Physikalische Therapie* By J Kowarschik (Pp 502 39 Swiss francs) Vienna Springer-Verlag 1948

A textbook of physiotherapy

*Submicroscopic Morphology of Protoplasm and its Derivatives* By A Frey Wyssling 2nd ed (Pp 255 32s 6d) London Cleaver-Hume 1948

An account of the chemistry, molecular structure and morphology of cytoplasm

*Sterility and Impaired Fertility* By C Lane Roberts C.V.O., M.S., F.R.C.S., F.R.C.O.G. et al 2nd ed (Pp 400 24s) London Hamilton 1948

Much new material has been included in this edition

*Snail's Progress. The English Local Prison* By C F Carter (Pp 28 1s) London Penal Reform Committee of the Society of Friends 1948

An account of English prisons based on the experiences of Quakers imprisoned during the recent war and since

*Proceedings of the Seth Gordhandas Sunderdas Medical College Staff Society* Meetings 45 to 55 and 56 to 66 (Pp 247 No price) Bombay Seth Gordhandas Sunderdas Medical College 1948

Articles on a variety of medical and surgical topics

*Blood Derivatives and Substitutes* By C S White M.D., Sc.D., and J J Weinstein, M.D., B.S. (Pp 484 \$7.50) Baltimore Williams and Wilkins 1947

An account of their preparation, storage, and therapeutic use, with a discussion of shock

*L'Exploration Clinique en Oto-Rhino-Laryngologie* By G Portmann (Pp 933 2500 francs) Paris Masson 1948

A general account of the examination of the ear, nose and throat

*Therapeutic and Industrial Uses of Music* By D Soibelman (Pp 274 16s) London Geoffrey Cumberlege 1948

A review of the literature with discussion and bibliography

*Science in Progress* Edited by G A Baitsell 5th series (Pp 353 27s 6d) London Geoffrey Cumberlege 1947

Includes articles by well known authorities on respiration, cytology and genetics

*The Issue of Compulsory Health Insurance* By G W Bachman and L Meriam (Pp 271 No price) Washington Brookings Institution 1948

A study of relevant conditions in the U.S.A.

*Cosmetic Materials* By R G Harry F.R.I.C. (Pp 479 35s) London Hill 1948

An account of the physical and chemical properties and dermatological action of cosmetic materials

*Nursing Pathology* By R H Goodale B.S. M.D. (Pp 416 15s) London Saunders 1948

An illustrated textbook for nurses

*Neuropsychiatry for Nurses* By I J Sands M.D. 5th ed (Pp 397 15s) London Saunders 1948

A textbook of neurology and psychiatry for nurses

*Oxford Science* General Editor F A Holland Vol 2 No 1 (Pp 53 2s) London Mowbray 1948

Intended to inform the scientist of recent progress in fields other than his own

*British Hospitals* By A G L Ivcs (Pp 50 5s) London Collins 1948

A short profusely illustrated account of British hospitals

ORGANIZATION OF CONSULTANTS AND  
SPECIALISTS

During the past weeks there has been much discussion on how to represent the interests of consultants and specialists in the National Health Service<sup>1</sup>. The need for an official machinery through which such representation can be made is not, of course, disputed. For the first time consultants and specialists have been faced with a problem familiar to general practitioners working under the National Health Insurance scheme for over thirty years. During this time much of the medico-political work of the B.M.A. has been concerned with the terms and conditions of service under the National Health Insurance Acts. For this reason these matters have loomed large in the debates of the Council and the Representative Body. And for this reason, too, general practitioners have been far more active in the work of the Association than have consultants and specialists. To meet the new need of specialists for representation of their interests as the result of the coming into force of the National Health Service Act, the B.M.A. quickly evolved a new mechanism by setting up regional and central committees through which consultants and specialists could organize effective representation and action on all those matters which will affect them in the Service. Some specialists have feared that their freedom of action in this field of work might be interfered with by a Council or Representative Body in which the interests of general practitioners are thought to be predominant. Those who express this fear fail to take into account the evolution of organized medical services in this country, or to allow for the continued development of the B.M.A.'s organization now that the whole of the medical services of Britain have undergone radical transformation. The Royal Colleges and the Royal Scottish Corporations have in the past functioned as academic and examining bodies. Since 1942 they have been inevitably drawn into the more controversial field of medical politics. Those in control of the Colleges and Corporations have been faced with a difficult decision—whether to continue to restrict their interests to academic work, or whether to enlarge them by taking an active part in medical politics. Those who are properly jealous of the traditions of these ancient pillars of Medicine have been anxious lest they should, by taking on functions that may involve them in medico-political controversy, lose the essence of the tradition which has made them what they are. Those with a more material concern in the economy of effort in a profession insufficiently manned for the

National Health Service deplored the possible emergence of a new medico-political organization for consultants in the presence of an experienced organization to which some 80% of the profession already belong.

Here then was a situation in which conflict of opinion might become acute. It is a tradition of doctors to disagree, but rarely to fratricidal lengths. An important step to solve tension and provide solution of the problem consultants and specialists are faced with was made on July 28 in a conference, presided over by Sir Lionel Whitby, President of the B.M.A., between representatives of the Royal Colleges, two of the Royal Scottish Corporations, and the British Medical Association. An agreed statement on the outcome of this conference is printed on page 351 of this issue. This highly important move is to be welcomed as a rational approach to finding an answer to the question of how best the interests of consultants and specialists shall be upheld in the National Health Service. An exploratory committee under the chairmanship of Sir Lionel has been set up to reach agreement on the three propositions submitted to the bodies represented at the conference. The first proposal is that a joint committee of the Colleges, the Corporations, and the B.M.A. shall be established to advise the Minister of Health on all matters affecting consultants and specialists. The second proposal is that the two existing committees—of the Colleges and the Corporations, and the Central Consultants and Specialists Committee of the B.M.A.—should continue as such to brief the Joint Committee. It will be essential to determine exactly to what extent these different committees shall take independent action, to define those matters in which they shall be autonomous. The third proposal of the conference, therefore, is that the Joint Committee shall clear this ground. It is desirable that the range of autonomy for the different organizations should be made unambiguous as soon as possible. Only by a clear definition will future misunderstanding be avoided and the interests of consultants and specialists be represented in a way that will facilitate prompt and effective action. The size of a problem, whether academic or medico-political, may determine the agency through which it should be tackled. For example, any big issue which may face consultants and specialists might be most appropriately dealt with by the Joint Committee representing the combined forces of the Colleges, the Corporations, and the B.M.A. But on the basis of its experiences in the National Health Insurance the B.M.A. would seem to be the most appropriate organization for dealing with the greater part of those matters coming under the heading of "terms and conditions of service." The supremacy of the Colleges and Corporations in academic medicine is undisputed.

The proposals put forward by the conference point a clear way out of a tangle of interests and of conflicting opinions. Given good will, and the evident desire on the part of everyone to reach a reasonable and friendly agreement, it should be possible through combined administrative experience and trained scientific thinking to isolate those facts in the situation which are important, to reject considerations which are irrelevant, and to put this matter of representation of the interests of consultants and specialists on a sound professional foundation.

## RECENT WORK ON THE Rh FACTOR

Theoretical aspects of the Rh factor and continued controversy on the nomenclature tend to obscure the steady advances which are taking place in the clinical application of knowledge already possessed. It should, moreover, be realized that these practical applications only very rarely require a knowledge of the finer theoretical points, important as these are to specialist laboratories and to the professional geneticist. Indeed, there is still much scope for clinical research on the Rh factor conceived in the original terms of simple Rh-positive and negative.

For some years clinicians and pathologists have been aware of the danger of giving transfusions, incompatible with regard to the Rh factor, to persons whose history suggests that they have been immunized to Rh either by transfusion or by pregnancy. Even in the absence of a history of immunization transfusion of blood of unknown Rh type into a woman of unknown Rh type may lead to grave results. This has not been so widely realized because the ill-effects may be long delayed. It is now known that in most, if not all, cases in which the first child is affected by haemolytic disease of the newborn the mother will be found to have had a previous transfusion. Many cases have come to light in which as a result of immunization by transfusion the mother has become unable to bear even one live child to her Rh-positive husband. It has indeed been suggested that the present increasingly frequent diagnosis of haemolytic disease of the newborn is not solely the result of improved facilities for investigation but is to a considerable extent due to the great increase in the use of transfusion which has taken place since 1939. Unfortunately, during most of this period the importance of Rh incompatibility was imperfectly appreciated.

Drs G Discombe and H O Hughes, in a paper appearing elsewhere in this issue (p 329), have thus performed a valuable service by drawing attention to reports which show how readily transfusion can produce Rh immunization and by supporting with statistics their opinion that the previous transfusion of mothers probably causes haemolytic disease of the newborn. They found that, whereas only 2% of unselected mothers at an antenatal clinic had had a transfusion, 36% of mothers of babies with haemolytic disease had been transfused. It can hardly be doubted that in most of the transfused mothers it was the transfusion which was the main cause of the disease in the child.

If further statistics should support these very striking figures it will be possible to state that about one-third of all the cases of haemolytic disease of the newborn at present occurring in this country are due to indiscriminate transfusion of mothers. Such transfusion must have a significant effect on the total infantile mortality of the country. It therefore ought to be a rigid rule that every female requiring transfusion, who has been or who may become pregnant, should be Rh tested. Hetero-haemotherapy of little girls, a procedure known to produce lasting immunization, ought probably never to be performed. Ideally, indeed, every recipient of a transfusion, whether male or female, should be tested and receive Rh-compatible blood. The National

Transfusion Service deserves every credit for its persistent encouragement of the Rh testing of all expectant mothers and transfusion recipients, but the responsibility for demanding Rh tests and seeing that only compatible blood is transfused lies primarily with the clinician in co-operation with the hospital pathologist. Limitations of supply preclude the easy way out of giving Rh-negative blood to untested patients.

It is not, however, sufficient that a clinician or hospital pathologist should be aware of the necessity for Rh testing or for the giving of Rh-negative blood, it is also necessary that the testing serum, or the blood, should be available. While it is only with the greatest of difficulty that sufficient Rh-negative blood can be made available for those cases known to need it, it is probable that few, if any, fail to receive Rh-negative blood if their need is known. On the other hand, the lack of Rh-testing serum is undoubtedly preventing much Rh testing which ought to be carried out. This state of affairs would be largely, if not wholly, remedied if every patient having a serum suitable for testing purposes and being in a fit state to give blood were given the opportunity of offering to make a contribution. Only by full co-operation between patients, clinicians, pathologists, and the transfusion service can this be brought about. At present a small though increasing number of enthusiastic medical officers are doing their best to maintain a supply for the whole country.

While it is probable that adequate arrangements for the collection of blood would produce a sufficient quantity of the relatively common types of serum needed for routine testing, there will probably always be a lack of the rarer types of serum required for special tests and for research. It may be necessary to look to the immunization of volunteers for this purpose. As more and more women known to have weak antibodies in their serum pass the menopause it will become justifiable to ask them to submit to further artificial immunization and to act as donors of serum, but it may be necessary meanwhile to look to male volunteers who have not previously been immunized. The investigations into the mechanism of Rh immunization reported by Dr J J van Loghem on another page are therefore of great practical value quite apart from the light which they may throw upon the mechanism of pregnancy immunization. Fourteen volunteers who had failed to respond to simple Rh immunization (by injection of appropriate red blood cells) received in addition injections of killed typhoid and paratyphoid bacteria. Three of them showed clinical signs of sickness and a rise in temperature. These, and these only, then produced Rh antibodies. Since van Loghem was using the relatively weak C and E antigens the proportion of responses must not be compared with the response in the same or other conditions to the powerful D antigen. Van Loghem has thus discovered a very useful technique for those who are attempting to prepare Rh antibodies in volunteers.

While successive theoretical advances in Rh research do not directly concern the clinician, their effect is in many cases to render transfusion potentially safer by eliminating rare but nevertheless dangerous types of incompatibility.

It thus becomes more and more important that when an anti-Rh serum has been obtained from an immunized mother or from some other source its constituent antibodies should be determined before it is used for routine testing. These necessary preliminary tests are beyond the scope of most laboratories, and the serum should be submitted to a specialist laboratory such as a regional transfusion laboratory or the Blood Group Reference Laboratory.

Professor D. F. Cappell's wide experience of both the clinical and pathological aspects of haemolytic disease gives special value to his survey of the Rh factor which appears on page 323 of this issue. It has been widely held that the first one or two affected children in a family show only mild symptoms, but Cappell has found that the first recorded manifestation of the disease is usually one of the severer forms. Bessis<sup>1</sup> has published details of a large number of families, and, while in many of them the first affected child suffered from icterus gravis, in others there was a progressive development of symptoms from one child to the next. Again, in the case of the incidence of cerebral damage and its response to transfusion, Cappell disagrees somewhat with previous workers and is of the opinion that such damage can in most cases be prevented by early transfusion.

In such matters as these the truth can be reached only by combining the observations of experienced workers, all who have access to large numbers of cases and are able to study them fully are under an obligation to publish their results. In many other matters connected with the Rh factor our clinical knowledge is inadequate, in particular more information is needed on the relation between parity of mothers and the time at which they first become immunized. This is a matter which can only be settled by combining the results obtained in large numbers of antenatal clinics.

## MENTAL HEALTH

In a world full of unrest, anxiety, and the mutterings of aggression the imaginative boldness of some outstanding medical men and organizations comes as a refreshing contrast to the futile bickerings of power-hungry politicians. It is, for example, a medical man, Sir John Boyd Orr, who has been the driving force behind the Food and Agriculture Organization (F.A.O.). Faced with one discouraging situation after another,<sup>1</sup> he yet retains his optimism that the nations of the world may yet show as much concern about the feeding of the 2,500 million people in the world as about feeding the 2½ million people in Berlin. As a result of Sir John's persistence a World Food Council has been set up. The conjoined attempt of medical men to promote world health through WHO is another example of inspired effort. And now comes the attempt to see what mental science can do for *Homo optimistically called sapiens*. A year and a half ago Dr G. Brock Chisholm, talking of the obligations of WHO in the sphere of mental and social health, said that WHO must derive its technical authority from the International Congress on Mental Health, the Congress which began its ten-day discussions

on Wednesday of this week. Those responsible for organizing this did not shirk the challenge, and in a statement of objects made shortly after Dr Chisholm's speech asserted roundly that "the general theme of the Congress will, therefore, be the psychological tasks involved in preparing the way for individuals to become citizens of the world." There is, perhaps, something naïve in this sentence, shorn of all qualifications and conveying to the reader the suggestion that those who framed it could scarcely have glanced over their shoulders at the past history of mankind. There is in these ambitious programmes a certain fine impatience with the impotence of the politician to deal with first things first, and as doctors we may be proud that through the specialized agencies of the United Nations medical men are trying to break down the customs barriers set up against health and knowledge.

The ground for the International Congress on Mental Health has been most carefully prepared by a series of commissions on the topics to be discussed. These commissions have been at work in Great Britain and in other countries so that the discussions now taking place can be of the fullest value to those attending and participating in them. This technique might well be adopted by the organizers of other international medical congresses. The present one is, in fact, a triad of three conferences—namely, on child psychiatry, medical psychotherapy, and mental hygiene. The first is focused on aggression, the second on guilt, and the third on psychological problems of the group. This sequence follows the aim of the organizers to apply to group, national, and international problems knowledge gained in the understanding and management of individual psychology. When he spoke about the conference in May of last year Dr Chisholm, seeing the significance of such an event, nevertheless asked this question: "Are psychologists and psychiatrists themselves individually and as a body able to do what I have just suggested? Can they, in fact, agree on anything?" And he went on to observe that it would be disastrous if the Congress were to "turn out to be a discussion of obscure psychological dogmata, or a conflict between various schools."

Speaking at the recent meeting in Edinburgh, reported elsewhere in this issue, Professor E. D. Adrian observed that neurologists, neurosurgeons, and physiologists are working on one side of a high wall and psychologists on the other. But he added that efforts were being made to break this down. Some demolition is needed on the psychological side too. Nevertheless, there is now a body of observed facts and some agreement among the schools on some of the hypotheses holding the facts together. To wait until knowledge of psychology is on a firmer ground of fact and theory before attempting to apply what is known on the ambitious scale the Congress has given itself might be to move in the direction of strict scientific caution, but to attempt what to some may seem to be the impossible brings with it at least a note of optimism in a world drenched with pessimism, and, so long as too much is not expected, much may be gained as the result of the discussions going on this week and next.

<sup>1</sup> See *The Listener*, Aug 5, 1948

## PROTECTING CHILDREN FROM TUBERCULOSIS

A recent question<sup>1</sup> in Parliament was aimed at finding out if the Ministry of Education now held any views about the employment of tuberculous teachers in schools different from the advice given in a joint memorandum<sup>2</sup> issued in 1927 by the Ministry of Health and the Board of Education. The Minister of Education informed the questioner that education authorities had again been reminded of the instructions in the memorandum. Since the document referred to was published over twenty years ago, long before mass radiography was practicable, and is now out of print, the present position can hardly be considered satisfactory, and the recent publication of a report<sup>3</sup> by the Children's Committee of the Joint Tuberculosis Council is timely.

The report is concerned with the means of protecting organized groups of children from the risk of infection by adults suffering from tuberculosis. These are its most important recommendations: (1) No person with pulmonary tuberculosis should be allowed to accept employment involving close contact with children until the disease has been certified as arrested. (2) All persons whose employment brings them into contact with groups of children should be medically examined at the time of their engagement, including x-ray examination of the chest, which should be repeated annually. (3) An employee found to be suffering from pulmonary tuberculosis should cease work immediately, and not be allowed to return to work until two medical certificates have been submitted, the first stating that the disease is no longer active and the second, after a further six months, stating that the improvement has been maintained. On returning to work the employee should be examined at three-monthly intervals for the first year and at six-monthly intervals for the next two years. (4) An unusually high incidence of tuberculous infection in a group of children should lead at once to a full investigation of the staff employed.

These recommendations are not of course intended to apply only to school teachers, but it is probable that local education authorities will be more interested in them than other public bodies. The problem of the school teacher who develops pulmonary tuberculosis and wishes to return to his or her previous employment is no easy one, and the strict enforcement of the Board of Education's old rule (which is similar to the first part of recommendation 3 above) has led to the disappointment and resignation of many good teachers who, even though successfully treated with artificial pneumothorax, may find it impracticable to remain unemployed while waiting for the required certificates. No doubt some of these have found work in private schools and it is to be hoped that those responsible for such schools will have a chance of studying the recommendations of the Children's Committee, which in any case are certain to receive the support of the school medical officers of local education authorities.

The report draws attention to the fact that in the past it has not been the practice to seek the source of tuberculosis in an infected child in the school which he attends, nor to investigate the school contacts of any teachers who may be discovered to have developed the disease. Hyge<sup>4</sup> has shown the dangers of this omission. In a State school for girls near Copenhagen in 1943 an influenza-like epidemic broke out almost explosively. A full investigation showed that 47 of the girls had developed pulmonary tuberculosis. The source of infection in all probability

was a teacher in whom the presence of pulmonary tuberculosis had not been recognized. An epidemic of tuberculosis in the Faroe Islands has also been reported recently, in this 22 patients were infected by a single girl. It is possible that the carrying out of the final recommendation of the Children's Committee of the Joint Tuberculosis Council might bring to light similar outbreaks in this country.

## NEW FACTORS IN SHOCK AND HYPERTENSION

In a series of papers a group of workers from Cornell University Medical College report the results of their investigations into certain of the problems of shock and hypertension. They have demonstrated the existence of two hitherto unrecognized blood-borne vasotropic substances which they have named vaso-depressor material (VDM) and vaso-excitor material (VEM). These substances are assayed by the following technique.<sup>1</sup> A rat meso-appendix is prepared for observation of its vessels, increasing concentrations of adrenaline are applied locally and the response of arterioles of a certain size is noted. The concentration of adrenaline needed to induce certain alterations in the circulation is taken as an end-point. The material to be tested—e.g., plasma—is now injected into the tail vein of the rat, and the adrenaline sensitivity is re-assayed. They find that this indirect technique based on the response to adrenaline is more reliable than directly observing the alterations in circulation in the meso-appendix that accompany the alterations in sensitivity to adrenaline.

VDM depresses the responsiveness to adrenaline, causes diminished frequency of vasomotion (contraction and relaxation) of the metarterioles and precapillaries, slows capillary circulation, and may cause a fall in blood pressure. VEM has the converse action and stops the circulation in some capillaries.<sup>2</sup>

The blood of animals (rats, rabbits, and dogs) in which shock was induced by tourniquet, leg pounding, Noble Collip drum, and by haemorrhage showed alterations which could be repeated, in the blood content of VEM and VDM as shock developed. When the animal was in mild or early shock its blood caused a 10- to 20 fold increase in adrenaline sensitivity on test preparations (VEM activity). Later the adrenaline sensitivity fell to well below that found with control animals, and this rise in VDM activity was associated with the development of irreversible shock which no longer responded permanently to fluid replacement therapy. By assaying extracts of organs of animals killed during various stages of shock<sup>3</sup> it was shown that VEM is produced only by the renal cortex, while VDM is produced by the liver and to a less extent by the spleen and muscle. The same workers also isolated the substances from these organs when they were incubated under anaerobic conditions. When incubated aerobically kidney destroyed VEM and liver destroyed VDM and to a less extent VEM.

Mazur and Shorr<sup>4</sup> have prepared VDM in a partially purified state such that 0.1 gamma can be easily assayed. It is apparently a protein of molecular weight 10,000 to 15,000, and iron appears to be an essential part of the active molecule. Less is known about VEM, but it appears to be distinct from renin or angiotonin.<sup>5</sup> Because of the circulatory change that VDM causes, it seems likely that it plays a part in the development of shock, but, as Chambers and Zweifach<sup>1</sup> themselves point out, so do other factors.

<sup>1</sup> *British Medical Journal* 1948 2 232.

<sup>2</sup> *Closure of and Exclusion from School* 1927. London: HMSO.

<sup>3</sup> *Report of the Children's Committee* 1948. Joint Tuberculosis Council, London.

<sup>4</sup> *Acta tuberc scand* 1947 31, 1.

<sup>5</sup> Poulgen A. *ibid* 1947 31 58.

<sup>1</sup> Chambers R. and Zweifach B. W. *Amer J Physiol* 1947 150, 239.

<sup>2</sup> Shorr E. *Amer J Med*, 1948 4 120.

<sup>3</sup> Shorr, Zweifach, Furchgott and Brier. *Factors Regulating Blood*. 1947 p 32. Josiah Macy Jr. Foundation New York.

<sup>4</sup> Mazur and Shorr *ibid* p 53.

<sup>5</sup> Furchgott and Shorr *ibid* p 60.

In an extension of this work Shorr *et al*<sup>3</sup> have shown that the kidneys produce VEM under the same circumstances as they produce renin in experimental Goldblatt hypertension, but there is an important difference in that VEM can be demonstrated in chronic experimental hypertension whereas renin cannot, for it apparently disappears with the acute phase. A curious and as yet unexplained finding is that VDM is also produced in chronic experimental hypertension and masks the VEM activity. To demonstrate the VEM it is necessary to incubate the plasma aerobically with liver to destroy the VDM. Of great interest is the finding by this technique that 12 patients with essential hypertension had raised amounts of VEM and VDM in the blood. What part, if any, these substances play in the genesis of essential hypertension remains to be seen, and this work raises the hope that the actions of VEM may explain much that dose of renin have failed to do.

### GENETIC COMPONENT OF LANGUAGE

In a recent paper C. D. Darlington<sup>1</sup> has made an original and thought-provoking contribution to the study of human genetics. He starts by emphasizing the importance of differences in language in maintaining mating barriers among human beings. Though a new language may be imposed upon subject peoples, and the stems of words and to a lesser extent grammar may remain relatively fixed, the phonetic complement—the sound equipment of a people—may reassert itself. There is evidence to show that this sound complement may well depend, at least in part, upon genetic constitution. The new speakers change the language in order to fit their preferences in sound production. There is no need to postulate any great difficulty—simply this measure of inborn preference “the tongue which prefers and adopts and the ear which later approves, the easy course”.

The simplest European variation which can be traced over the centuries with considerable accuracy is the presence or absence of the Th sound. This sound was present in the common ancestral Indo-European language, expanded westwards, where it met a Th-speaking Basque one, and in the East it met non-Th-speaking peoples. Later there were successive movements into Europe from the East of peoples who did not have Th. In eastern Europe this sound was lost in prehistoric times. From 300 B.C. to 1400 A.D. the loss spread from Italy through France and Germany to Sweden. To-day in Europe Th persists only along the fringe—Iceland, Great Britain, Spain and Greece, being retained to a variable extent in western Norway, Denmark, and a few smaller outlying areas. The remarkable point that Darlington brings out is that maps showing the distribution of Th and of the ABO blood groups correspond with a faithfulness that is startling. It should be explained in passing that Darlington relies on the distribution of blood-group gene O. Previous writers have almost invariably prepared maps showing variations in gene A and gene B, gene O being left as the unmapped difference. Apparently this has served to obscure the kind of relationship now brought out. It is true that Haldane<sup>2</sup> used triangular co-ordinates for plotting the three gene frequencies simultaneously, but this is a device which is not readily understood by the non-mathematical. Darlington's maps show that with little exception the peripheral European one from Iceland to Greece has 65% to 75% of gene O and also possesses Th. The intermediate zone with O ranging from 61.5% to 64.5% stretches from Sweden to France and corresponds to the area where Th was once

present but has now been lost. The main eastern zone and the Portuguese sector of the Iberian peninsula have less than 61.5% of O and never had Th. The only exception to complete correspondence in the maps is that Italy and Holland have not retained Th.

The contrast between Portugal and Spain in both maps is particularly striking. On the one side we see 61% gene O and complete absence of Th, on the other 65–69% gene O and a determined reintroduction of Th after a period of conquest by a non-Th people. The gradient between Greece and her neighbours is also sharp—56% gene O and no Th on one side of the mountain barrier, 68% gene O and Th on the other. The finer differences in the British Isles are in conformity with the association. The maxima of both variables occur in Ireland, falling through Scotland and Wales to northern England and finally to minima in the south-east, where Th tends to be replaced by D in Kent and by V or F in London. Apparently the oldest non-Th speakers remain as the outermost fringe of all—i.e. in Portugal. There is also a region of variable Th in western Ireland. The Th speakers in turn have been pushed outwards by the non-Th speakers from the east. Phonetics, blood groups, and history are all in harmony and point to the same conclusions. It is clear that Dr Darlington has produced weighty evidence for a genetic component in language and has called attention to methods of study in human and population genetics that should yield very valuable results in the future.

### INDEPENDENT DOCTORS

Lord Horder, in a recent letter,<sup>1</sup> criticized the Council for its handling of the situation which developed after April 7. He said: “There are many doctors asking for guidance, not only for themselves but for their sons and daughters thinking of medicine as a vocation.” And to these he added many members of the public and “men who will leave the Service they have too hastily joined out of fear and not conviction.” Lord Horder went on to invite readers to send him their views privately. According to a long report in the *Observer* of Aug 8 consultants and general practitioners have begun discussions in London this week “to create an organization for doctors who have chosen to remain outside the National Health Service.” According to the *Sunday Times* this is the outcome of the letter Lord Horder, who is to take part in the discussions, wrote to the *Journal* on June 19. Lord Horder is reported to have said to the *Sunday Times* correspondent that as he was a member of the Council of the B.M.A. he would “hesitate before setting up another body outside that organization.” The *Observer* states: “Those who will take part in this week's discussions consider that the independent doctors must be organized for mutual protection and assistance, and must be ready to assist the B.M.A. in any future opposition it may give to further State encroachments on the traditional practices of the profession and essential rights of its patients.” According to this newspaper many of the independent practitioners believe that increasing numbers of patients will seek medical attention outside the scheme, and believe, too, that the Government will welcome their assistance.

It would seem improbable that Lord Horder would signalize his first year in office as a member of the Council of the B.M.A. by helping to create an organization outside it. If those taking part in this week's talks feel that some kind of “watch committee” is necessary to represent the interests of those staying outside the National Health Service there would appear to be no reason why such a committee should not be set up for this purpose in the B.M.A.

## PERITONEOSCOPY

BY

JOHN HOSFORD, MS, FRCS

*Surgeon St Bartholomew's Hospital*

My object in writing this brief article is to make a plea for the wider use of the peritoneoscope. Although the possibility of peritoneoscopy as a method of examination of the abdomen has been known for many years it has been used surprisingly little in this country. Indeed, it is remarkable that it has not become one of the standard endoscopic methods used in every hospital where general medical and surgical work is done. I have most frequently gained help from the peritoneoscope in the diagnosis of disease of the liver and in recognizing metastases in the abdomen. Clinically it is often difficult to distinguish between a malignant liver and cirrhosis, but by the comparatively simple procedure of peritoneoscopy the diagnosis is easily settled. By the same means metastases can readily be recognized in the omentum, intestines, parietal peritoneum, etc.

It is an everyday experience for the abdomen to be opened for exploration of a carcinoma and to find metastases in the liver or elsewhere. The surgeon has carried out an unnecessary operation and is as deserving of blame as if he had explored a bladder without first cystoscoping the patient. It is not so many years since I witnessed a surgeon (inexperienced in the use of the cystoscope) opening a bladder to remove what he from the radiographs thought was a stone, when really the case was a beautiful example of calcification in a uterine fibroid. The crime of opening the abdomen and finding the case inoperable owing to the presence of metastases is committed daily in this country by surgeons inexperienced in the use of the peritoneoscope.

I would urge most strongly, therefore, that surgeons should become as familiar with the use of the peritoneoscope as they are with the cystoscope. It is undoubtedly easier to interpret the view seen in a peritoneoscope than that seen in a cystoscope or gastroscope, yet it remains a most singular fact that extraordinarily little attention has been paid to peritoneoscopy.

## History

Kelling in Germany in 1910, using a cystoscope, was the first to report an attempt at peritoneoscopy, the instrument carrying its own light—although Ott, a Russian, in 1901 was the first to look into the peritoneal cavity through a small opening, but he used a speculum and head-mirror. Various further makeshift peritoneoscopes were done, using cystoscopes, sigmoidoscopes etc., but it was not until Ruddock, of Los Angeles, published his papers in 1934 and 1937 describing his peritoneoscope that a wider interest in the subject was aroused. Since then many papers have appeared in the American medical literature, but very little has been written on the subject in this country. The first to make an important communication were Prof. Milnes Walker, of Bristol, and Mr. Playfair in 1942. Peritoneoscopy was the main subject of the evening at a meeting of the Royal Society of Medicine in 1943, the opening speakers being Prof. Milnes Walker and Dr. Cooke, of Oxford, who clings to the name laparoscopy. I can find no article on peritoneoscopy in the *British Medical Journal*, except a brief note on the subject in 1925 by Rendle Short, who used the word "coeloscopy" and employed a cystoscope.

## Technique

The procedure consists in distending the abdominal cavity with air, which is introduced through a cannula inserted with the help of a trocar a little distance above the pubes in the midline. The abdomen is fairly tightly distended so that the abdominal wall is firm. An incision about  $1\frac{1}{4}$  in (0.6 cm) in length is then made a little distance below the umbilicus in the midline, and the peritoneoscope, held very firmly, is slowly pushed through into the peritoneal cavity. The air has lifted the abdominal wall away from the intestines and omentum so that these are not injured if reasonable care is taken. The introducing trocar of the peritoneoscope is then withdrawn from the sheath, and the telescope, which carries a light on its

end, is passed down the sheath, into which it fits with an airtight washer. The examination of the cavity then proceeds.

I have used a Ruddock peritoneoscope since 1938 on numerous occasions, about an equal number of examinations being done under local analgesia and general anaesthesia. Intravenous thiopentone is quite satisfactory as a general anaesthetic. Under procaine local analgesia many patients do not complain at all, though others resent the abdominal distension with air, and a few experience some pain when the instrument rubs against the parietal peritoneum as it is moved about inside the abdomen. When the examination is finished as much air as possible is let out through the sheath, which is then withdrawn, and the tiny opening is closed with one stitch. There is no need for the patient to remain in hospital.

The procedure is carried out in an operating theatre with full aseptic ritual, and it is of much convenience to have a table which tilts into the Trendelenburg and reverse Trendelenburg positions. The instrument is inserted below the umbilicus because this makes it easy to see both sides of the upper abdomen by passing it first on one side of the falciform ligament and then on the other. Adhesions may cause trouble in moving the peritoneoscope about. It is dangerous to insert the instrument into the abdomen close to a previous incision as intestine may be adherent to the abdominal wall at that point and so be injured.

The information that can be derived from the view obtained is of course not by a considerable measure so great as that which can be got from a laparotomy. Only the anterior surface of the structures in the anterior part of the abdomen can be seen, though by inserting a slim straight metal rod through a separate puncture in the abdominal wall the edge of various structures can be raised and a view obtained under them. Information of the greatest value can, however, be obtained. It is possible to see nearly the whole of the liver, the fundus of the gall-bladder, the anterior wall of the stomach and most of the colon, the omentum, much of the small intestine, and the parietal peritoneum. The spleen is difficult to see unless it is enlarged, and only very seldom can the appendix be seen. In a steep Trendelenburg position one can often inspect the depths of the pelvis, though sometimes the small intestine will not come up out of the way.

Complications of peritoneoscopy are insignificant. The majority of patients have no after-effects whatever. A small area of surgical emphysema appears around the puncture site in an occasional case. In only one case was it at all extensive, spreading to most of the abdominal wall, in a few days subsided without any untoward result.

When introducing the preliminary trocar and cannula for the pneumoperitoneum care has to be taken to make sure it has gone through the parietal peritoneum as well as the abdominal wall. Sometimes the peritoneum is very loosely attached to the abdominal wall and gets pushed forward, with the result that when air is pumped in it strips the peritoneum up over

1, Trocar and cannula for pneumoperitoneum 2, Outside sheath of the peritoneoscope 3, Trocar for introducing the sheath 4, Telescope

very wide area and causes an internal surgical emphysema this makes further examination most difficult. No instance of injury to gut or viscera has occurred in any of my cases and in none has there been haemorrhage or sepsis.

### Summary

A strong plea is made for more frequent use of the peritoneoscope. The technique and the application of peritoneoscopy are briefly outlined.

## INTERNATIONAL CONGRESS OF PSYCHOLOGY MEETING IN EDINBURGH

The Twelfth International Congress of Psychology, originally planned for 1940, was held in Edinburgh from July 23 to 29, and was attended by over 600 members from most European countries, the United States, Canada, China, India, Chile and elsewhere. The programme covered a wide range of subjects, with the main emphasis on cerebral function, social and industrial psychology, and child psychology. One of the striking features of the discussions was the high proportion of time devoted to the borderlands between physiology, neurology, and psychology. As Professor Adrian said the neurologists, neurosurgeons, and physiologists were working on one side of a high wall and the psychologists on the other. It was clear, however, that determined efforts were being made in several countries to break this wall down and to link psychological concepts to neurologic findings.

Professor SYDNEY SMITH, acting Vice-Chancellor of the University of Edinburgh, welcomed the members of the Congress on July 23 and expressed great regret that Professor Emeritus James Drever, president of the Congress, was unable to be present owing to illness. In his absence the inaugural address was read by his son, Professor JAMES DREVER, and took the form of an interesting historical survey of the development of philosophy or introspective psychology, in Scotland during the past two centuries from David Hume's treatise on *Human Nature* in 1739 to the present time.

### Cerebral Function

Professor E. D. ADRIAN spoke on the physiological mechanisms of the brain. He said that though neurologists and neurosurgeons had most to say about recent developments in the physiology of the nervous system, a description of some of the general reactions of nerve cells and the activity taking place in them was of interest to psychologists. Most important was the great amount of activity in the nerve cells that made up the higher levels of the nervous system. There was a constant cycle of physical changes, and the mechanism of rhythmic discharge was highly developed with a wide range of frequency. The stimulus of the sensory endings caused instability sufficient to give a continuous discharge of low frequency. In the brain constant activity was the rule. Although greatly reduced by an anaesthetic or sleep it could be brought back by a single stimulus. (This was demonstrated by amplified recordings from the olfactory bulb of a fully anaesthetized rabbit.) There was some evidence to show that consciousness (behaviour) depended on the cells of the brain having some degree of instability, which made them of constantly changing receptivity. The cells of the cortex had a spontaneous constant changing activity. At a lower level in the spinal cord there was less evidence of changing activity—reflex centres must behave with complete obedience to orders. The cells of the brain were not so obedient; conscious activity being less predictable.

Professor O. L. ZANGWILL (Oxford) dealt with the subject of visual orientation in relation to cerebral dominance. It had long been known that lesions involving the parieto-occipital region of the cerebral cortex were liable to provoke marked and characteristic disturbances of visual space perception. The principal types of disability hitherto described were (a) visual disorientation, which might be complete or incomplete according to whether the responsible lesion was bilateral or unilateral, (b) disturbances in visuo-spatial articulation and in the apprehension of high-grade spatial relations in the visual field, and (c) distortion of the main co-ordinates of visual space. Disorders of the second and third type were particularly common in cases with right-sided parieto-occipital lesions, and he tentatively suggested that some mechanism of special significance for visual space perception was located in the minor hemisphere. Preliminary evidence in support of this view based on the comparative psychological study of cases with right-sided and those with left-sided parieto-occipital lesions, was discussed in some detail. The relation of visual object-agnosia to lesions of the dominant hemisphere, and of topographical memory loss to lesions of the minor hemisphere was also briefly considered. In the light of the available evidence Professor Zangwill concluded that object and colour recognition, and the simultaneous grasp of a complex perceptual field, appeared closely bound up with the activity of the dominant hemisphere, whereas the general framework of spatial relationships seemed to depend to a much greater extent on the contribution of the minor hemisphere. It appeared, therefore, that the principle of cerebral dominance applied to some at least of the processes subserving visual cognition in general.

### Electroencephalography

Dr T. C. BARNES (Philadelphia) described the physiological and psychological factors in electroencephalography. There were many physical, chemical and psychological conditions that affected brain-waves. It was probable that the electrical activity of the brain was produced by phase-boundary potentials generated by acetylcholine at the interface between brain lipid and tissue fluid. This cholinergic theory suggested that parasympathetic activity might be associated with increased electrical activity of the brain, and, conversely, that signs of sympathetic activity might accompany decreased activity. Also, the vasodilatation of cerebral vessels produced by acetylcholine might promote bio-electrical potential. Evidence for this theory was found in the following investigations. In a group of normal persons whose EEG became abnormal on hyperventilation the skin temperature of the hand fell an average of 1.6°C and pulse rate rose 35 beats, compared with an average fall in skin temperature of only 0.6°C and pulse rise of 23 beats in normal persons whose EEG was unaltered by hyperventilation. These results supported the theory of parasympathetic control of the encephalogram. In addition to physiological studies it had been found that psychological tests also aided in the interpretation of the EEG, and it was useless to record brain-waves without careful study of all possible cholinergic and psychogenic elements. (Throughout the reading of this paper many of the points were strikingly illustrated by a volunteer who was connected to an electroencephalograph, the resulting record being circulated as a continuous tape among the audience.)

### Prefrontal Leucotomy

In a symposium on this subject a paper by Professor G. JEFFERSON (Manchester) was read by a deputy. After a review of the beneficial effects of lobectomy in lesions of the frontal lobe, and a discussion of frontal lobe function, the effects of leucotomy were considered. Bilateral frontal lobe damage, whether caused by tumours, injury, or lobectomy, gave rise to certain faults such as lack of initiative, lack of normal inhibition in emotional behaviour, and inability to learn new tasks. These faults were also liable to occur after leucotomy, but fortunately the changes were not so apparent in the majority of cases as to make a deep impression on either the patient or his relatives, who in favourable cases are so much impressed by his greater tractability that faults are minimized or overlooked. It was impossible to give a clear-cut account of what happened after leucotomy, owing to the fact that each patient was an individual behaving according to his own personality and his own environmental and genetic history, but observations on a series of 70 cases had shown that those patients did best who, before they became mentally deranged to a point requiring active treatment, had had time to acquire distinct personalities. Thus, patients suffering from depressive states, and those developing delusions or paranoia late in life, would be more likely to improve after leucotomy than the schizophrenics. One tiresome sequel to leucotomy (commonly

presented in pure frontal lesions) was incontinence during consciousness, this might persist for six months or more

Dr E STENGEL (Chichester) suggested that prefrontal leucotomy would be of only historical interest in years to come when more refined techniques were available. Its effects in terms of physiology or psychology could not be defined but only in terms of personality change. The effects were reduction of spontaneity, lowering of emotional tensions and less ability to maintain emotional tensions, decrease of social responsibility, and a general lowering of the level of behaviour. Sometimes restlessness was produced. Leucotomy acted in two ways—by causing changes in certain mechanisms involving the prefrontal lobes, and as a powerful shock treatment. Good effects were produced in chronic depressive states. The chronic stress of schizophrenia could be turned to contentment, without however enabling the patient to be discharged. Changes of personality were dependent not so much on the extent or site of the lesion as on the patient's previous personality.

Dr W MAYER GROSS (Dumfries) maintained that prefrontal leucotomy not merely balanced but extinguished psychotic symptoms, and the problem for the future was to produce as much reduction of psychotic symptoms as possible with the minimum of prefrontal lobe deficiency. He described one patient who had recurrent attacks of catatonia, which were temporarily stopped by insulin, shortened by shock therapy (which also increased their frequency), and permanently (so far) removed by leucotomy.

Dr A A W PETRIE (London) gave a preliminary report on the results of the psychological investigation of patients following prefrontal leucotomy. Tests were given prior to operation and two and six months post-operatively and in a preliminary analysis at the first retest after leucotomy changes were noted in tests of persistence, muscular control, self-blame, speed and suggestibility.

Dr A MEYER (London) described the results of examining 97 brains of leucotomized patients who had died, and discussed the effects of the operation according to the relation of the cut to the fibres connecting with the thalamus and hypothalamus. He concluded that patients who do badly and die soon after operation usually have an unduly posterior cut. The degree of personality change seemed to be associated with the number of fibres cut. The less desirable changes appeared with unduly posterior cuts. Cutting the central orbital fibres was of importance in producing an effective result.

Dr M A PARTRIDGE (London), describing the effects of leucotomy, said that in the early weeks urgency and frequency of micturition or dribbling of urine were often noted. The early picture was of increased fatigability and reduced activity, but patients could be energetic when interested. With time normal activity returned more than did normal restraint. Patients were thus less keyed up, more placid, and less restrained. They developed a "selective carelessness," not doing things they were not keen to do, and avoiding effort and discomfort. Hypochondriacal symptoms disappeared. The effects of leucotomy were dependent on the previous personality.

Dr K GOLDSTEIN (New York) said that in measuring the performance of patients who had had prefrontal leucotomy, psychologists must not rely on the total scores for tests, but should study the way in which these were achieved. Many patients succeeded in more difficult but failed in easier tests. The key to the intellectual changes following leucotomy lay in the loss of the power of abstraction. Concrete performance was not so much impaired. Good social adjustment was due not so much to increased social co-operation as to reduced self-criticism. Such patients seemed restricted in personality and abnormally dependent on the outside world and there was a need to reconstruct the patient's life. The question was whether an operation of this kind was justified when it deprived the patient of his essential nature.

#### Problems of Ageing

Dr A T WELFORD (Cambridge) surveyed the work of the Nuffield Foundation research unit established at Cambridge in 1946 under the direction of Sir Frederic Bartlett. From a preliminary interpretation of the findings of investigations into differences of skilled performance associated with different age groups it appeared that the principal locus of change lay within the central mechanisms. On the receptor side there was an

increasing difficulty among older subjects to comprehend or organize a visual field or set of presented data. On the effector side there were differences of method of building or organizing a response. These changes of method appeared to compensate fairly effectively for deficiencies in many cases so that measurements of total achievement did not give at all an adequate picture of the changes of performance.

In addition to the very full daily programmes, special evening lectures were delivered by Dr H S LANGFELD (Princeton) on "American Psychology To-day," by Dr A MICHOTTE (Louvain), and by Sir FREDERIC BARTLETT (Cambridge) on the "Challenge to Experimental Psychology."

### CENTRAL HEALTH SERVICES COUNCIL

As we stated last week, the Minister of Health, Mr Aneurin Bevan, has announced the members of the Central Health Services Council, of which we give a list below. One appointment has still to be made. Mr Fred Messer, M.P., has been elected chairman, and Professor Henry Cohen vice-chairman. The secretary is Mr E J S Clarke, of the Ministry of Health.

*Ex-officio*—Lord Moran, President of the Royal College of Physicians of London; Lord Webb-Johnson, President of the Royal College of Surgeons of England; Sir William Giliatt, President of the Royal College of Obstetricians and Gynaecologists; Dr Harry Guy Dain, Chairman of Council of the British Medical Association; Sir Herbert Lightfoot Eason, President of the General Medical Council; Dr George Frederick Buchan, Chairman of the Council of the Society of Medical Officers of Health.

*Medical Practitioners*—Dr Janet Aitken, physician (London); Professor William George Barnard, pathologist (London); Mr Aleck W Bourne, obstetrician and gynaecologist (London); Dr James Alexander Brown, general practitioner, member of Birmingham Regional Hospital Board (Birmingham); Sir Ernest Rock Carling, surgeon (London); Professor Henry Cohen, physician, member of Liverpool Regional Hospital Board and Board of Governors (Liverpool); Dr Edward Andrew Gregg, general practitioner, member of County of London Executive Council (London); Dr Wilfred Vivian Howells, general practitioner, member of Swansea Executive Council (Swansea); Dr Horace Jules, physician and medical director, member of NW Metropolitan Regional Hospital Board and of Hammersmith, etc., Board of Governors (Middlesex); Professor Aubrey Julian Lewis, psychiatrist, member of Bethlem and Maudsley Hospital Board of Governors (London); Dr William Gordon Masefield, psychiatrist, member of SE Metropolitan Regional Hospital Board and of Bethlem and Maudsley Board of Governors (Sussex); Dr William Norman Pickles, general practitioner, member of Yorkshire North Riding Executive Council (Aysgarth, N York-shire); Professor Sir Harry Platt, orthopaedic surgeon, member of Manchester Regional Hospital Board and Board of Governors (Manchester); Professor James Calvert Spence, paediatrician, member of Newcastle Board of Governors (Newcastle upon Tyne); Dr Clement Willoughby Walker, general practitioner, member of Cambridge Executive Council (Cambridge).

*Persons with Experience in Hospital Management*—Mr Frank John Cable, superintendent, Manchester Royal Infirmary (Manchester); Mr Sydney Clayton Fryers, house governor and secretary General Infirmary at Leeds, member of Leeds Regional Hospital Board (Leeds); Hon Arthur Jared Palmer Howard, Chairman of St Thomas's Hospital Board of Governors (London); Sir Owen Frederick Morsherd, member of NW Metropolitan Regional Hospital Board (Windsor); Major General Sir Harold Augustus Wernher, Honorary Secretary of King Edward VII Hospital Fund and Chairman of University College Hospital Board of Governors (London).

*Persons with Experience in Local Government*—Alderman Albert Frederick Bradbeer, member of Birmingham Regional Hospital Board, Board of Governors, City Council, and Executive Council (Birmingham); Sir Wynne Cemlyn Jones, member of Anglesey County Council and Executive Council (Anglesey); Mr F Messer, chairman of NW Metropolitan Regional Hospital Board and Middlesex County Council, member of Middlesex Hospital Board of Governors and Middlesex Executive Council (Middlesex); Mrs Dorothy Thurtle, member of London County Council and Shore-ditch Borough Council (London); Alderman William E Yorke, Lord Mayor of Sheffield, member of Sheffield Regional Hospital Board (Sheffield).

*Dental Practitioners*—Mr Frederick J Ballard, member of NW Metropolitan Regional Hospital Board, University College Hospital Board of Governors, and Eastman Dental Clinic Board of Governors.

(London) Mr J Lauer, member of Dental Estimates Board  
(London) Dr Harry Thomas Roper-Hall (Birmingham)

*Persons with Experience in Mental Health Services*—Sir Cecil Oakes, member of East Anglian Regional Hospital Board (Suffolk)

*Registered Nurses*—Miss Eleanor Jeannette Merry, education officer, Queen's Institute (London) Miss Mary Elizabeth Gordon Milnc, matron, St Mary's Hospital (London)

*Certified Midwife*—Miss Nora Bryan Deane, matron, Bristol Maternity Hospital (Bristol)

*Registered Pharmacists*—Mr Richard Henry Henriksen, chief pharmacist, Dulwich Hospital (London) Alderman William John Tristram, member of Liverpool City Council and Executive Council (Liverpool)

## INTERNATIONAL CONGRESS ON INDUSTRIAL MEDICINE

### PROGRAMME OF LONDON MEETING

The ninth International Congress of Industrial Medicine will be held in London from Sept 13–17, and a preliminary programme has been issued. The opening of the congress will take place in the Central Hall, Prince's Street, Westminster, on Sept 13, at 11.30 a.m., when the chairman will be Lord Moran, and the Rt Hon G A Isaacs, M.P., Minister of Labour and National Service, will give the inaugural address. The chairman at the closing of the congress on Sept 17 will be Lord Webb Johnson, and an address will be given by the Rt Hon G R Strauss, M.P., Minister of Supply. Further information about the congress can be obtained from the organizing secretary, Room 501, B.M.A. House, Tavistock Square, London, W.C.1. The meetings will be either in the Caxton Hall, Caxton Street, Victoria, S.W., or the Alliance Hall, Palmer Street, Westminster, as shown in the summary of the programme given below.

*Monday Sept 13 2.30 p.m.* at Caxton Hall, Studies in Atmospheric Pollution, Industrial Nursing, Organization of Industrial Medical Services, Industrial Medical Content of the Law at Alliance Hall, Diseases of the Lungs other than Pneumoconiosis

*Tuesday Sept 14 10 a.m.* at Caxton Hall, Work and Skill, Environment—Lighting, Aetiology and Treatment of Surgical Conditions found in Industry, Training of the Industrial Medical Officer, at Alliance Hall, Industrial Nursing 2.30 p.m., at Caxton Hall, Environment—Architecture, Aetiology and Treatment of Surgical Conditions found in Industry, Radiant Energy—Hazards and Prevention, Toxicology, at Alliance Hall, Hazards and Aspects of Specific Industries

*Wednesday Sept 15 10 a.m.* at Caxton Hall, Medical Supervision in Industry, Pneumoconiosis (1), Ophthalmology Toxicology, at Alliance Hall, Organization of Industrial Medical Services 2.30 p.m., at Caxton Hall, Environment—Thermal Comfort, The Newer Metals, Organization of the Industrial Medical Service, Pneumoconiosis (2)

*Thursday Sept 16 10 a.m.* at Caxton Hall, Integration of Occupational Health with National and Community Services, Dermatology Preventive Methods in Mining, Aetiology and Treatment of Surgical Conditions found in Industry, at Alliance Hall Environment—Applied Physiology 2.30 p.m., at Caxton Hall Occupational Tumours of the Bladder Pneumoconiosis (3), Hazards and Aspects of Specific Industries Industrial Electricity

*Friday Sept 17 10 a.m.* at Caxton Hall, Incentives, Job Adjustment and Absenteeism, Pneumoconiosis (4) Hazards and Aspects of Specific Industries, Symposium on Colour Vision, at Alliance Hall, Toxicology

The Mackenzie Industrial Health Lecture on 'The Surgeon in Industry' will be delivered by Mr H E Griffiths at B.M.A. House, Tavistock Square, London, W.C., on Friday Sept 17 at 5.15 p.m.

The programme also includes a list of places of technical interest to which visits will be paid during the week of the congress and the following week. Those wishing to be included in any of these visits should obtain Form IC/6 from the secretary of Section V of the congress at the address of the organizing secretary.

## ORGANIZATION OF CONSULTANTS

### FORMATION OF JOINT COMMITTEE

A conference of representatives of the Royal Colleges, two of the Royal Scottish Corporations, and the British Medical Association was held at the Royal College of Surgeons on Wednesday, July 28, to discuss the general question of the organization to represent consultants in the future. Sir Lionel Whitby, President of the B.M.A. presided. After discussion it was decided to submit to the bodies invited to the Conference the following propositions:

(i) That a Joint Committee of the Royal Colleges, the Royal Scottish Corporations and the British Medical Association be established to advise the Minister of Health on all matters concerning consultants and specialists.

(ii) That the existing Committee of the Colleges and Corporations and the Central Consultants and Specialists Committee established by the British Medical Association continue in existence to brief the Joint Committee.

(iii) That the Joint Committee be requested to allocate, as soon as practicable, fields in which their constituent bodies are free to take independent action and to deal with Governmental bodies direct.

It was agreed to establish an Exploratory Committee of nine members with Sir Lionel Whitby as Chairman.

[The above is the subject of a leading article at page 343.]

## BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

The following elections for 1948–9 are announced:

*Senior Fellowship (£900 a year)* F Sanger, B.Sc., to study the structure of proteins, with special reference to insulin (at the Department of Biochemistry, University of Cambridge).

*Junior Fellowships (normal value £600 a year)* D A Darcy, B.Sc., to study the role of the lymphocyte and plasma cell in homograft breakdown (at the Department of Zoology and Comparative Anatomy, Oxford), R M C Dawson, B.Sc., to study biochemical changes in the brain associated with different forms of functional activity (at the Biochemical Laboratories, Cardiff City Mental Hospital), F N Fastier, M.Sc., to study the nature of the musculo-tropic action of basic amide derivatives (at the Department of Pharmacology, University of Oxford), L J Haynes, Ph.D., to study the synthesis of the coenzyme cozymase (at University Chemical Laboratory, Cambridge) A T James, Ph.D., to study the relationship between structure and biological activity in naturally occurring substances (at the Lister Institute of Preventive Medicine, London), A McCoubrey, B.Sc., to study analgesic and addictive tendencies from a chemical standpoint (at the Departments of Organic Chemistry and Pharmacology, University of Leeds), S W Stanbury, M.B. Ch.B. to study the effect of changes in nervous activity induced by narcosis and sleep on the renal circulation and blood pressure in normal and hypertensive individuals (at the Department of Medicine, University of Manchester), D Verel, M.B., B.Ch., to study the postural hypotension which may follow prolonged rest in bed (at the Clinical Research Unit, Guy's Hospital, London).

Regulations issued by the Secretary of State for Scotland empower local authorities under the National Health Service to provide services which go beyond the ordinary measures of health care. These include the supply of layettes and clothing for babies and mothers, meals at day nurseries, cots, beds, and bedding for people needing them on health grounds, and invalid chairs or invalid carriages. Because authorities might sometimes hesitate to provide items of this kind to people able to pay for them, the Health Service (Scotland) Act empowers the Secretary of State to allow authorities to make charges in this connexion. These regulations—the National Health Service (Local Authority Charges) (Scotland) Regulations, 1948—specify the items for which charges may be made if particular authorities wish to do so. Even where an authority decides to charge it can make a reduction where a person is unable to pay the authority's standard charge. Charges under the regulations may be either for outright supply or for supply on loan. In the latter case, and where they supply on loan other items such as ordinary nursing appliances for which no charge is allowed, authorities can make it a condition that loss or damage due to carelessness shall be paid for by the person responsible.

## Preparations and Appliances

### THE CURATOR HEEL

MR KENNETH H PRIDIE, Bristol, writes In these days there is considerable delay in getting corrective alterations even of the simplest type done to shoes. It seemed to me that it was obvious that there must be a mass-produced heel which could be quickly applied to a shoe by any competent repairer. A new heel which embodies a simple corrective device for use in cases of unbalanced and pronated feet—the condition generally known as "valgus feet" (Fig 1)—is now being made by Messrs

FIG 1

FIG 2

C and J Clark, Ltd, of Street. This heel, which is made of moulded rubber, has the advantage of a half-elongated heel with a one eighth inch inside wedge, (Fig 2). The moulding has an improved support on the waist of the shoe which reinforces the upper so that it is not deformed by the pressure of a flat foot. The increased support has been found very effective in difficult cases, in fact a patient with a severe valgus deformity due to muscle imbalance was able to dispense with the outside irons and inside T straps previously needed to maintain correction.

The advantage of this appliance is that if elongation and wedging of the heel is necessary the elasticity of the heel is unaltered, in fact it is improved. Most shoes in which the heel has been elongated and wedged become so rigid that the foot is splinted and the natural movements impeded. However, with this moulded rubber heel the foot is supported, "in-rolling" corrected, and excessive rigidity of the shoe avoided (Fig 3).

FIG 3

After consultation with the surgeon or doctor, the parent should take the child to be correctly fitted by the nearest retailer stocking Clark's shoes in the full range of sizes and widths. These retailers are equipped with a special device for measuring the feet to ensure that a shoe is selected that gives the fullest amount of support combined with room for toes to grow. When the correct shoe has been selected the retailer will arrange immediately to have the normal leather heels removed and the "curator heel" fitted. The retailer will arrange this either in his own repair department or by sending the shoes to the factory to have the work carried out. In either case the time taken should only be a matter of days.

## Correspondence

### Diabetic Coma

SIR—In the *Journal* of July 24 your wise editorial comment (p 209) on the papers on diabetes appearing in the same issue will be welcomed by all those experienced in the treatment of the condition. It is doubtful, however, whether the very mild though telling criticism which it contained on certain of the views expressed in the respective papers of Dr G M Wauchope (p 191) and Professor R H Micks (p 200) will be universally appreciated. Perhaps our experience, which is fairly extensive may help to underline some of the observations made in your leading article and may also sound a warning note to those who may be tempted to follow implicitly the regimen suggested by your contributors.

We have given globin insulin a thorough trial since it was first introduced, and though we have found it a most useful preparation in many patients suffering from mild or moderate diabetes it has proved entirely unsuitable when used alone in a great many cases of greater severity. To suggest as Dr Wauchope does, that it is the insulin of choice in almost all ambulant cases of diabetes is an exaggeration which would only lead to the misuse of the preparation and to the consequent inadequate control of diabetes in a high proportion of patients. It seems to us essential for clinicians to be fully aware of the limitations of globin insulin if the incidence of complications is not to increase.

There is much in the article by Professor Micks on the treatment of diabetic coma which is valuable and worthy of the closest attention. The necessity of aspirating the stomach contents and of giving adequate amounts of saline solution rapidly by the parenteral route needed to be stressed. We find ourselves, however, quite unable to agree with the dosage of insulin which he recommends. We fully appreciate that for too long there has been a general tendency to use quite inadequate amounts of insulin in this emergency and undoubtedly many lives are lost on this account but to go to the other extreme and to advocate such doses as 500 units initially, followed by 100 units as often as every ten minutes if improvement is not manifest within an hour, is in our opinion highly dangerous advice.

It is certainly true that an initial large dose is needed in order to overcome the resistance to insulin which is so marked a feature of diabetic coma. It is equally true that if the initial dose be inadequate insulin resistance will persist and may actually be increased. As was first pointed out by Joslin, insulin given within the first three hours is considerably more effective than a similar dose spread over a longer period. In the majority of cases, however, 100 units given initially followed by 100 units one hour and two hours later is sufficient to cause a rapid increase in sensitivity to insulin and to bring about a sharp fall in the blood sugar level. When excessive loading doses are given, hypoglycaemia results, which in an unconscious dehydrated patient is not always as easy to recognize as Dr Micks would suggest. Using the doses suggested by him such hypoglycaemia is bound to be a common occurrence, especially in the hands of inexperienced physicians in circumstances which do not permit of careful blood sugar control. While the author acknowledges that such cases may be expected he dismisses hypoglycaemia as a minor complication which is easily remedied. In doing so we believe him to be minimizing a very real danger, and that to precipitate a patient already severely shocked into hypoglycaemia may prove fatal in certain cases.

In our experience the insulin dosage recommended by Professor Micks as a routine procedure is seldom necessary and should never be used by those inexperienced in the treatment of diabetic coma. That he is able to advocate it with such confidence would seem to indicate that his patients are more insulin-resistant than most of ours. According to his previous papers the patients under his care are taught to control their diabetes by insulin alone, without much dietetic restriction. In our clinic the great majority of patients are treated not only by insulin but by fairly meticulous control of their carbohydrate and calorie intake. It is possible, though by no means certain, that

this difference in dietetic control may account for the altered insulin-sensitivity exhibited in coma by the two groups of patients—We are, etc.,

D M DUNLOP  
J B DONALD

Edinburgh

SIR—Professor R H Micks (July 24, p 200) stated, "As far as I know there is no record of a patient ever having passed from diabetic coma into a fatal hypoglycaemic attack." The implication is that this does not happen, but such a conclusion is hazardous. I would suggest that hypoglycaemia in the energetic treatment of diabetic coma, without facilities for frequent blood sugar estimations or utilization of such or without the concomitant use of glucose, is common and is occasionally fatal. I have certainly met with it when emergency treatment, particularly over week-ends, was in the hands of relatively inexperienced hospital residents. Publications of such cases may be advisable, but too much significance should not be attached to their absence.

At a 1947 endocrine conference, when I spoke of the dangers of overdosage with desoxycortone three doctors informed me of their experience of acute adrenal insufficiency being transferred into fatal hypopotassemia, and expressed their appreciation that the danger had been aired. Existing publications hardly reflected such experiences. Hormones are indeed powerful agents and overdosage no less a danger than timid inadequate therapy—I am, etc.

London W 1

S L SIMPSON

SIR—The following case illustrates two points in Professor R H Micks's article (July 24, p 200)

The patient, a girl of 21 years, was admitted to hospital with a 7 months' history of great lassitude and amenorrhoea, she had had a boil on her buttock for 10 days. Retrosternal oppression and increased laboured respiration had been present for 12 hours. Temperature was 101.5° F (38.6° C), pulse 144, respirations 28. Her face was flushed, mouth parched, tongue red and dry, there were no chest signs, the heart was normal, the abdomen resistant. The patient was not comatose, and diagnosis of hyperglycaemia was only made after the urine had been examined and was found to be loaded with albumin, sugar, and acetone. Further questioning disclosed thirst and polyuria for seven months, blurring of vision for some weeks, and pruritus vulvae for two days. Blood sugar was 400 mg per 100 ml, and the BSR was 62.

The orthodox treatment of insulin and glucose was commenced with 50 units of soluble insulin and 50 g of glucose by mouth at 9 a.m. and repeated at half these doses two-hourly. The patient grew worse throughout the day, vomited 18 oz of dark-coloured fluid at 9.30 p.m., and became comatose. An intravenous dextrose saline was then given. Her rapidly worsening condition gave rise to anxiety, and the dose of insulin and glucose was stepped up to 25 units and 20 g hourly, and then half-hourly, until a total of 750 units of insulin had been given. Meanwhile catheter specimens of urine were examined with each dose for fear of hypoglycaemia. The large doses of insulin were administered as a desperate and final measure and were considered a gamble.

With a total of 750 units by 7 a.m. the following morning the patient showed marked improvement. Blood sugar had fallen to 85 mg per 100 ml, though the urine still showed sugar +++ (3%). Three days later she had a fasting blood sugar of 296 mg per 100 ml, which rose to 405 mg one hour after glucose and was 367 mg after 4 hours. Sugar +++ and acetone ++ were found in each specimen of urine during sugar-tolerance test. Further progress was uneventful.

This case is of interest as demonstrating Professor Micks's points of the dangers of too conservative an administration of insulin and of gastric dilatation. Large insulin dosage at an early stage would have been safer. Glucose was given both by mouth and intravenously in liberal amounts in accordance with current usage. The withholding of glucose in diabetic coma is a modern departure and an interesting one—I am, etc.,

Starchley, Birmingham

ROBERT J D BROWNE

SIR—To me it appears that Professor R H Micks (July 24, p 200) implies that injection of insulin into the tissues of an 'inaccessible' diabetic patient is devoid of danger. What else can he mean by advocating that "the doctor called to a case of coma should always give at least 100 units before even ordering the ambulance"? Perhaps the context makes it sufficiently

clear that his advice to general practitioners supposes competence to differentiate between diabetic coma and insulin reaction. Without presuming to give an opinion on the reasonableness of this supposition, I venture to record the impression gained as a hospital resident that many doctors are unwilling to attempt clinical diagnosis of the unconscious diabetic patient, and to suggest that the advice quoted above is not devoid of danger.

I have in mind an instance which may be without parallel but not without moral. A doctor summoned to the patient of a colleague (who was away) found a diabetic man unconscious. The doctor gave insulin and reassurance. Some four hours later the doctor prescribed more insulin and a hot-water bottle. Four hours after that the patient arrived in hospital, where consciousness was shortly restored with intravenous glucose. The patient recovered from his hot-water bottle burns in a fortnight and from the empyema which complicated his pneumonia in a further six months. When the doctor who had prescribed the insulin was told the history of the case, the only comment was, "At least my insulin did him no harm."

May I submit that Professor Micks's counsel to the general practitioner should be reworded: "The doctor called to a case of coma should always order the ambulance before giving any insulin"?—I am, etc.,

BRIAN WEBBER

### Pain in Phantom Limbs

SIR—In their letter (July 31, p 267) Dr R E M Bowden and Dr J R Napier put forward a point of view that I think should not be allowed to pass unchallenged. They state that cases of phantom limb pain should be divided into two separate and distinct types according to whether pain is (1) burning in character or (2) stabbing, shooting, or tingling. (They do not mention that in addition to these various degrees of cutaneous pain patients with phantom pain also experience deep muscle and joint pain.) Their view is, I realize, a commonly held one, but several reasons can be given for disagreeing with it.

1 *Experimental Observations*—Among the many interesting observations on pain sensation made by Sir Thomas Lewis and still not sufficiently well known, one was that exactly the same type of cutaneous stimulus could produce either burning pain or a stabbing, pricking sensation, the result depending entirely on the intensity and duration of the stimulus. A brief stimulus gives rise to "pricking" pain, a more prolonged stimulus to "burning" pain, and this is always so in whatever way cutaneous pain is provoked. In other words, the difference between burning pain and a stabbing, pricking, or tingling sensation is merely a difference in intensity and does not necessarily involve any difference in the nature of the causative lesion.

2 *Clinical Features*—In addition to patients who have constant burning pain in a phantom limb and those who have constant stabbing, pricking, or tingling sensation, there are many who, while they usually have a pricking or tingling sensation, experience burning pain during periods of exacerbation of pain such as commonly occur in these cases. There are also patients who generally do not suffer from any type of phantom pain but at intervals have attacks of pricking pain or of burning pain. And in many patients who have severe burning pain for some weeks or months after amputation the severity of the pain gradually lessens, so that later they have a stabbing, pricking type of pain, and later again experience even this type of pain only at intervals. It seems impossible to regard these different types of phantom pain as indicating different conditions, for that would imply that one condition could change for a period into another. The more reasonable view would seem to be that the nature of the condition remains the same, the only change being variation in intensity of pain. Moreover tender neuromata may be present in patients with burning pain as well as in patients with less severe pain, and in both groups pressure on tender neuromata causes exacerbation of pain. Such associated features as cutaneous tenderness, cyanosis, and hyperidrosis are as a rule prominent only in severe examples of the condition with burning cutaneous pain and usually also severe muscle and joint pain.

3 *Response to Sympathectomy*—Dr Bowden and Dr Napier state that patients with the less severe type of pain are unlikely to respond to sympathectomy. I carried out sympathetic procaine blocks in several patients of this group and found that in them, just as in patients with severe burning pain, this produced immediate relief in some and not in others. Subsequent operative sympathectomy was, however, practically never carried out in patients without burning pain, as in these patients the phantom sensation was seldom unpleasant enough to make them anxious to undergo a major operation for its relief.

For these reasons, then, I regard all cases of phantom pain as being similar in origin and mechanism of production, whether they have burning pain or not. It is, however, possibly not altogether desirable for the word "causalgia" to be used to describe all these cases with their varying painful sensations, or even for the term "minor causalgia" to be used for the less severe examples. As pointed out by Dr Bowden and Dr Napier, Weir Mitchell originally coined the word "causalgia," meaning literally "fire pain," to describe only the single symptom of burning pain, and it might still be desirable to use it only in this sense, or at least only for cases with this type of pain, without of course implying that there is any difference in pathogenesis between this "causalgic" pain and lesser degrees of pain following nerve trauma—I am, etc

### Fibroma of the Labium Majus Complicating Pregnancy

SIR—It must be very rare for tumours of the vulva to reach such a size during pregnancy that they constitute a possible difficulty in labour. The following report describes the occurrence of such a tumour.

#### CASE REPORT

A Muganda woman came to the hospital in October, 1947, to await her confinement. She had had two previous normal deliveries and was then about eight months pregnant. It was a vertex presentation, and there was no disproportion. From the vulva hung an elephantoid mass the size of which can be gauged from the accompanying photograph.

This mass had first appeared in January, 1947, and the patient must have become pregnant very shortly afterwards. As the tumour was likely to cause obstruction to delivery it was decided to perform caesarean section at term, and then remove the mass later. Accordingly on Nov. 19, 1947, when labour had just begun, a classical caesarean section was carried out.

Three weeks later, on Dec. 12, 1947, the tumour was removed. It was found to be arising from the right labium majus, with a broad pedicle extending up to the right of the symphysis pubis. The mass weighed approximately 5½ lb (2.4 kg). Recovery was uneventful but the patient insisted on leaving hospital before the perineal wound had completely healed.

Dr R. B. Baird, of the Medical Laboratory Kampala, reported on the tumour as follows: "Consists of a mass of fibro-fatty tissue in which there are fairly numerous dilated lymph vessels. I can find no evidence of lymphogranuloma or of filariasis, but cannot definitely exclude the latter. Probably a fibroma."

My thanks are due to Dr R. B. Baird for his pathological report and to Dr Hebe Welbourn for the photograph.

Kampala, Uganda

W R BILLINGTON

### Acute Intussusception in Childhood

SIR—The interesting and thorough paper by Drs Brenda Morrison and Donald Court (April 24, p. 776) brought to my mind an experimental and clinical study on the subject made by my former chief, Dr W. Obadalek, which appeared in 1929 in *Bruns Beiträge zur klinischen Chirurgie* (146, 668). Its clinical part is based on 53 cases of intussusceptions in infants and children ranging in age from 3 months to 13 years, 28 of them under 2 years old. They were treated in the surgical wards of the Children's Hospital in Brno (Czechoslovakia) between 1910 and 1928. Since 1921 the number of infants among the material increased steadily, apparently because the condition was more frequently diagnosed by the general practitioner.

Obadalek's diagnostic observations concur with those of Morrison and Court and so do the results of treatment, which in 50 cases was surgical. A diagnostic "pointer" which Obadalek stresses is dullness on lumbar percussion of the supine patient which disappears after he has been turned on the opposite flank, thus indicating free fluid in the abdominal cavity. He found it in all cases of his material, and its great value in his opinion lies in the fact that it helps to differentiate non-surgical diseases—e.g., dysentery, purpura, constipation, alimentary intoxication—from abdominal conditions requiring surgical attention. In doubtful cases a diagnostic enema (without x-ray) often produced blood where none had been observed before.

The high proportion of intussusceptions in childhood—53 out of a series of 101 cases of ileus treated altogether in that period—Obadalek explains by (1) stronger intestinal peristalsis and more irritable intestinal mucosa in children, (2) the unequal growth of ileum and colon, resulting in a difference in diameter between ileum and colon, which is most marked in infants of 4–6 months, and (3) a mobile caecum frequently found in infancy and early childhood. The intussusception, he believes, is initiated by a localized intestinal spasm. In 15 out of his 50 operated cases congenital or inflammatory changes were found in the intestine concerned, or in its vicinity: 4 polypi, 3 Meckel's diverticula, 1 tuberculous ulcer and 7 cases of inflammation of the appendix ranging from chronic disease involving the regional lymphatics to gangrene.—I am, etc,

Derna, Cyrenaica

F BARBER

### Filariasis

SIR—The initial clinical manifestation of *Loa loa* may only appear several years after infestation with the parasite, and infected individuals may not develop symptoms until after taking up residence in this country. Furthermore, as these symptoms are thought to be due to an allergic reaction to toxic products of the worm resulting in urticarial eruptions and painless swellings in the subcutaneous tissues, either localized (Calabar swellings) or diffuse, the condition may be diagnosed as angioneurotic oedema, and the underlying cause passed unrecognized. The following case report may be of interest.

A male, aged 26, was referred to hospital on April 7, 1948, because of a painless swelling of the left arm of 5 days' duration, and itching of the left shoulder. There was no history of relevant illness in childhood or adolescence, and the family history showed no proneness to allergic disorders. He had served in Southern Nigeria from 1943 to 1946, with only a few months' interval in 1944, and had had eight attacks of malaria. Repatriated in November, 1946, he had been fit and had worked up to the present illness.

On general examination he was well nourished, all the internal organs were normal. Slight conjunctival injection and palpebral swelling in the left eye was noticed. There was uniform swelling with no tenderness and with only slight pitting on pressure of the left axilla, arm, forearm, and hand. A mild papular eruption could be felt over the pruriginous area. There were no nodules. He was recommended to take "anthisan," 200 mg 3 times a day, and to report in one week's time. The swelling did not subside with this treatment, and he was therefore admitted on April 15.

The history of prolonged residence in Southern Nigeria led us to suspect African filariasis, more commonly known as *Loa loa*, but no microfilariae were seen in the blood films taken on numerous occasions over a period of several days. A concentration test was also negative. Blood counts, however, showed on repeated occasions a high total leucocyte count, 21,000–32,000, with a marked eosinophilia of 51.5%–65%. The laboratory of the London School of Hygiene and Tropical Medicine kindly performed a complement fixation test with dirofilarial extract, and this was found to be positive.

The swelling slowly subsided and had practically disappeared by April 24, there remaining only a palpable gland in the left axilla. The patient was discharged on April 26. On April 30 the painless, diffuse swelling reappeared in the left supraclavicular region and shoulder. It disappeared on May 4. The patient was later transferred to another hospital for chemotherapy.

The diagnosis of *Loa loa* was based in this case upon the following significant points: (1) the occurrence of angioneurotic symptoms in an individual who had returned from a filarial region in West Africa, (2) the finding of leucocytosis with very high eosinophilia, and (3) the finding of a positive complement fixation reaction with dirofilarial extract. A skin test with the extract, often positive in the disease, was not carried out in this patient, under the mistaken impression that it might not be

### Compensation for Industrial Injuries

SIR—I would like to draw attention to a point in the National Insurance (Industrial Injuries) Act which will cause much dissatisfaction among employees. A man is adjudged to be recovered from a disability when he is able to enjoy the normal amenities of life and to return to work. It does not state that he is able to return to his *original* work. Thus a skilled worker, say for instance a french polisher, would not be entitled to any disability pension once his dermatitis has disappeared, even though he could never return to his highly paid job, because he is now fit to undertake labouring work. I believe there may be some small payment up to one pound in special cases, but nothing comparable with that under the Workmen's Compensation Act.

The only method open to the workman is to bring an action against the employer based on negligence, a very unsatisfactory and hazardous procedure. Even under the old Act the employee is often very dissatisfied, and one feels that he will be much more so unless some new arrangements can be introduced.—I am, etc.,

Leeds

F F HELLIER

### Standardization of Stretchers

SIR—I was much interested in the article by Lieutenant-Colonel R. T. Wells (June 26 p. 1246) on this subject, and I heartily agree that steps should be taken to standardize both the stretchers and the tracks in the ambulances themselves. As one who has taken an interest in ambulance work for over thirty-five years and who has had considerable experience with the fitting and maintenance of ambulances in peacetime and during the late war in civil defence, I feel, like your correspondent, that a common policy should be adopted, especially just now when the various health authorities under the Health Act, either directly or, as in some counties through their agents the St John Ambulance Brigade and the British Red Cross Society, are acquiring new vehicles.

I feel, too, that not enough use is made of the telescopic-handle type of stretcher, so useful not only in hospital lifts but also on awkward stairways where a carrying sheet is not practicable, but this should not lead to ambulances being built with a shorter inside body measurement than 7 ft 10 in., otherwise interchangeability may be impracticable.

My view also is that the tracks for the stretchers to run in should be of the following type: on the side nearest the body of the vehicle both near and off L-shaped and that on the inner side near the gangway should be simply L-shaped. The vertical arm in each case should be towards the other track, unless of course the L-shaped tracks are made wide enough to allow for the difference of the width in the runners themselves or the actual width of the stretcher, so also giving a margin for the possible splaying of the stretcher in wear.—I am, etc.

Weston-super-Mare

HUGH POWELL

### Needles for Varicose Veins

SIR—The needles here illustrated have been used by me continuously since October, 1946. Their purpose is to abrade the interior of the internal or external saphenous vein at the operation of ligation of varicose veins. The larger extending needle is passed down the saphena magna from the groin and will occasionally travel to its full length—i.e. to well below the knee. The skin is pressed down over the rough end of the needle with the fingers and by short up and down movements

the venous endothelium is mechanically scarified thus ensuring rapid thrombosis, which will be followed by resolution and permanent obliteration of the internal saphenous trunk where it has been so treated. The smaller needle is inserted at the internal malleolus and usually passes up to the knee. This section is similarly lacerated internally.

These needles fit a Record syringe so that sclerosing fluids can also be introduced. Both sections of the extending needle are made to fit a Record syringe. The roughened ends have been arrived at by repeated experiments with Messrs. Down Bros., to whom I am indebted for their courtesy and assistance. I was introduced to this endothelial destruction by Dr. Field who had seen it used by Mr. Riddoch, of Birmingham, who kindly presented me with his needle. By their use only a small volume of sclerosing fluid is required and permanent destruction of the internal or external saphenous veins is certain.—I am, etc.

London W 1

HAROLD DODD

### Twin Pregnancy and Hydramnios

SIR—We should be grateful to Dr. R. W. Danziger (July 24, p. 205) for his note on twin pregnancy with acute hydramnios, for, as Browne points out, acute hydramnios is very rare. How rare I do not know, but in this hospital, where we see 1,400 deliveries annually, I have seen only one such case in five years. This would explain why textbooks of obstetrics hardly mention the treatment of puncture of the uterus.

Dr. Danziger says that there is no objection to repeating the process. I would go further than this and say that the puncture of the uterus should be repeated again and again provided it can be shown by the tape measure that the girth of the abdomen is constantly increasing. If it is not repeatedly aspirated, then there is a very great danger that the membranes may rupture spontaneously and the woman may die of the shock produced by the sudden liberation of gallons of fluid, to which may be added a post-partum haemorrhage.

The late Mr. Carnac Rivett's observation that the fluid is not under pressure is not borne out by my experience either. It is under great pressure and will continue to pour out of the cannula for as long as required. In my case first 7 and then 8 pints were aspirated.—I am, etc.,

### Control of Treatment

SIR—The recent controversy upon the importation of BCG for use in this country either by those who are convinced of its value, or alternatively for use only by some who would conduct a controlled five- to ten-year trial, raises a point of great pertinence.

BCG has been used over many years and detailed results have been published by men of high repute in many countries. On the basis of these reports many in this country have already concluded in its favour. They would say that the proposed trial would be an unjustifiable deprivation to many who would otherwise receive BCG and a restrictive control applied in the field of preventive medicine. The other group finds reason to doubt the validity of the published statistics and wishes trials to be repeated on lines more acceptable to our statisticians. A compromise might be reached by providing clinical material through certain institutions for a long-term trial and at the same time allowing physicians of standing in the tuberculosis field to use BCG as they thought fit. By either of the last two schemes a black market would probably be created.

Be that as it may, and admitting the existence of two opinions on the subject, there is still an even more basic principle involved. The Ministry of Health would appear at present to be considering restriction of the use of a new treatment in this case prophylactic, by means of restriction of import. This raises the question as to whether new drugs and treatments should be tried out by whoever wishes, or in some cases be at first restricted to special research trials. This is a matter which is of great importance to clinical medicine and of no concern in the first instance to administrators. It should therefore be settled by a body representing the profession and not by a Ministry. Indeed the administrative mind is likely to introduce cross currents into a discussion which ought to lead

to a decision based solely upon scientific considerations. When that basic decision has been taken, then we are still faced with the question as to whether this or that new drug should be the subject of restricted trial or not. Again I say that only a purely professional body should take these decisions and not the Ministry of Health. It is a short step from restriction of import from abroad by the Ministry to control of the distribution of home-produced drugs.

The Ministry can in this instance apply control because we do not produce BCG ourselves, but it would be wrong to allow this particular case to develop further without realizing what is involved—control in the clinical field by the Ministry, advised by professional men of its own choice, or control of such therapeutic trials by a wholly professional body for whose decisions the Minister and his administrative department do not have to be responsible—I am, etc.,

Stanmore Middlesex

HARWOOD STEVENSON

### Use of Ring Pessaries

SIR—The provocative condemnation of the ring pessary by Mr Mortimer Reddington (July 24, p 227) was doubtless intended to stimulate interest and discussion about this admirable appliance, and I need no further apology for my remarks, dogmatic though they be.

The stink and dangers of pessary treatment may be entirely eliminated if no ring is fitted which cannot easily be withdrawn and if rubber instruments are abandoned. The only indication for the watch-spring pessary is in the treatment of occasional cases of incarcerated retroverted gravid uterus, when it may be used for a short period of time. A light vulcanite or plastic ring may be used with advantage in those cases of puerperal prolapse in which exercises and physiotherapy fail to prevent descent of cystocele or cervix outside the vulva, decreasing sizes of ring may be fitted at short intervals to ensure that support is effected by pressure on the levatores ani without interference with the involution of the vaginal fascia. Similarly an early menopausal prolapse may sometimes be controlled so well with a ring for a few years that subsequent vaginal contraction may make further treatment unnecessary. The temporary value of the ring for patients awaiting operation, and for those who desire to postpone surgery for domestic or social reasons is common knowledge, while a not inconsiderable number of patients may express great satisfaction and decline operation.

There are uses too for pessaries other than the hard ring. An acquired post-partum retroversion may on occasion be responsible for symptoms, and it would appear rational to correct such malposition as a routine, fixing the uterus with a Hodge-type pessary until involution of the pelvic fascia has made such support unnecessary. This pessary may also be used as a diagnostic measure, to determine which symptoms in any given case of retroversion may be expected to be relieved by an operation for anteversion. Then there will always be a few cases of utero-vaginal prolapse in old women who are barely fit for operation, which may be well controlled by the Simpson shelf pessary. Finally, despite Mr Mortimer Reddington's gloomy emphasis, it may be possible greatly to relieve stress incontinence of micturition by fitting a Hodge pessary turned upside down and back to front, as demonstrated by Professor Chassar Moir—I am, etc.,

W G MILLS

### Osmoreceptors

SIR—Professor E B Verney (July 17, p 119) infers from his findings that "osmoreceptors" exist in the brain, and suggests experimentation on their precise localization and histological identification. It is generally accepted that physiological and pathological swelling of the brain may be reduced by hypertonic saline or sucrose injections, and that the shrinkage is balanced by an influx of blood to the brain. The increase of cerebral blood flow under such conditions lessens synaptic resistance (*British Medical Journal*, 1938, 1 265), and therefore more neuronic stimuli per unit time reach the supraoptic nuclei to activate the posterior pituitary and give an antidiuresis—I am etc.

Birmingham

F A PICKWORTH

### Chemists' Working Hours

SIR,—I am obliged to Mr H W Tomski (July 17, p 177) for his assurances and the figures he adduces in support of his arguments, both all too familiar and fallacious. If few people took advantage of the experimental late opening it was because few people or doctors knew about it. Even now it was hard to find a chemist who exhibits in his window the rota list after closing hours, except in Paddington, where an excellent rota is carried on. It is for the doctors to bestir themselves in their own areas to ensure an efficient pharmaceutical service.

There can be no doubt that the public are suffering unnecessary hardship as a result of the 6 p.m. closing of chemists. The pharmacists must clarify their status. Either they are shopkeepers pure and simple or members of a profession with dignity and concomitant responsibility. If the latter, they should not shelter behind the Shop Hours Act, which in any case does not apply to dispensing. Let the rota be efficiently run and publicized, and the chemists will not need to complain that they are wasting their time by late opening—I am, etc.

### Hearing-aids

SIR—May I through your columns make the position clear regarding hearing aid supplies? We are, at our acoustic branches, receiving a considerable number of callers with EC 10 prescriptions, some of which are specifying that the patient be supplied with a "National hearing aid", others prescribe that the patient's existing hearing-aid shall be repaired under the health scheme, and still others call for supplies of hearing-aid batteries.

The Government has chosen to leave hearing aid manufacturers such as ourselves outside the scheme, and therefore we are not in a position to accept prescriptions for any hearing aid supplies other than those for which the patient is prepared to make payment. It seems unfair that existing users of hearing aids are not to get assistance under this new comprehensive service towards maintaining their instruments, but it remains for the deafened public to make representation in the proper quarter if they wish to get this apparent anomaly rectified—I am etc.,

### POINTS FROM LETTERS

#### Treatment of Pneumonia

DR MALCOLM TATE (Mansfield, Notts) writes. The *Journal* of July 17 (p 157) contains an interesting summary of the discussion on the treatment of pneumonia at the annual meeting of the B.M.A. There is no mention in it, however, of what many of us feel to be an important part of this treatment. We consider that all patients who have been successfully treated for pneumonia must have a final chest x-ray examination before we can say that they are cured. Only in this way can we discover any underlying pulmonary disease, such as bronchial carcinoma or atelectasis, and such sequelae as a small pleural effusion or incomplete resolution. We may by a timely x-ray hope to increase the operability of bronchial carcinoma, which is so deplorably low at present. It is for this reason above all others that I advocate the accessibility of the x-ray departments to the general practitioner now, not when health centres are built.

#### Analgesia in Midwifery

DR ALEX WATT (Dulry, Ayrshire) writes. It was with much interest and some amusement that I read the proceedings at the combined meeting of the Sections of Anaesthetics and Obstetrics dealing with the position of analgesia in midwifery (*Journal* July 17, p 155). I consider it amusing that a specialist anaesthetist should be required to conduct analgesia. Such a qualification alone is insufficient for the purpose, but would require to be combined with a thorough knowledge of women in labour, and that of many hundreds of cases, and in general practice. It is not at all likely that all women will be admitted to hospital for confinement, therefore the conduct of labour and the exhibition of analgesics must necessarily fall on the general practitioner. Analgesia can be perfectly satisfactory in every case provided the obstetrician or general practitioner has a knowledge of all the agents and can concoct a suitable cocktail for the individual case.

## Obituary

### C M KENNEDY, MBE, FRCS

Mr Charles Matheson Kennedy, who died at his home in North Bovey, Devon, on July 26, was one of the best known and respected of Plymouth surgeons. He was born at Moville, Co Donegal, in 1884 and educated in England at Saint Edward's School Oxford and the London Hospital. He qualified in 1906, and held resident appointments at the London Hospital, at one time being house surgeon to James Sherren, until obtaining the FRCS in 1911. He was then appointed a surgical registrar, a post he held until the outbreak of the 1914-18 war when he at once joined the Army. Most of his service was spent in France, where he was employed as a surgical specialist. At the close of the war he was commanding the limb-fitting hospital at Rochampton with the rank of lieutenant-colonel. He was awarded the MBE for his services.

After the war he settled in Plymouth, being appointed assistant surgeon to the hospitals now combined as the Prince of Wales's Hospital. He commanded for a time the Wessex Field Ambulance, T.A. In due course he became full honorary surgeon to his hospital and was elected to the staffs of a large number of associated cottage hospitals in the Plymouth and East Cornwall area. He was also orthopaedic surgeon to the Plymouth Orthopaedic Hospital under the Plymouth City Council and to the Dame Hannah Rogers Children's Orthopaedic Hospital at Ivybridge. It can be judged from the number of these appointments that he was a very much employed man. He was an able and bold surgeon, his technical ability being reinforced by sound judgment in diagnosis and procedure. During the last war he did an immense amount of work among the air raid casualties in Plymouth and travelled hundreds of miles, often in conditions of considerable danger.

Charles Kennedy's services to the B.M.A. were manifold and given without thought of his own affairs. He was a past president of the South Western Branch and past chairman of the Plymouth Division in which capacity he served throughout the war. His advice was constantly sought and always valuable, accentuated by that particular brand of humour which made his points so emphatic. He was also a great Mason. He held the office of Senior Grand Warden of Devonshire, was a member of three Lodges, of two of which he was a Past Master and of one a Founder. He was in much demand as an after-dinner speaker and will long be remembered for his fluent and witty speeches, one of which was the highlight of the Annual Dinner of the Association in 1938. His untimely death at the age of 64 found him still in harness and full of interests outside his professional work. He was a talented gardener and a keen fisherman and shot. His loss will be felt widely, not only his professional colleagues but a host of friends deplore his passing and a multitude of grateful patients will miss his cheery presence and his universal kindness. To his widow and four sons, two of whom follow in his footsteps, goes out the sincere sympathy of all who knew him.

### W ARNOTT DICKSON, MD FRCS Ed

Dr William Arnott Dickson for many years a well-known figure in the life of Gloucestershire died at Thames Ditton Surrey after a short illness, on July 25. Though he had retired and had been living in Scotland since 1944, the announcement of his death has come as a shock to the many who enjoyed his friendship and relied on his wise counsel. Arnott Dickson graduated M.B. Ch.B. at St Andrews University in 1904. The range of the higher qualifications with which he soon afterwards equipped himself is significant of the high standards he set for himself and of the breadth of his outlook on medicine. He obtained his FRCS Ed in 1907, his MD in 1908, his DPH in 1910 and his MRCP Ed in 1923.

After gaining experience as a house-surgeon and practising in partnership with his brother the late Dr David Dickson of Iwerley, Fife, he became Tuberculosis Officer to the Fife County Council. In 1913 he settled in Gloucestershire as County Tuberculosis Officer with which post there was combined a few years later that of Medical Superintendent of the

Standish House Sanatorium. It was Arnott Dickson who organized and developed the whole county tuberculosis service from its small beginnings. His relationship with the Joint Board for Tuberculosis, which administered that service, was a very happy one. He enjoyed the confidence and esteem of the members in quite exceptional measure. Yet there was in him nothing of the public official. He was essentially a physician and one with whom the individual and his personal problems counted most. His colleagues throughout the county placed great reliance upon his opinion both as a consultant and as a friend. Throughout his career he also took a prominent part in medical affairs in the county. A member of the B.M.A. since 1905, he was honorary secretary of the Gloucestershire Branch from 1922-30, president of the Branch in 1930-1 and a Representative from 1937-43.

Arnott Dickson had a vigorous, efficient and well stored mind. He combined a genial disposition and a buoyant wit, which was never long concealed. With all his popularity he was entirely without self-seeking or affectation and he found his greatest happiness in his home life, where he was ever the kindest of hosts. But it is also true of him to say that underneath his attractive social qualities there lay something in reserve depths of feeling and of reverence from which he drew inspiration for his sane and healthy attitude to life.

On his retirement in 1944 he was presented with a silver bowl subscribed for by members of the profession in all parts of the area—a tribute to the respect and affection in which he was held. He is survived by his wife and two daughters, both members of the medical profession, to whom great sympathy will be extended.

### WILLIAM ROBERTSON LOGAN, MD FRCP Ed

Dr William Robertson Logan died at Edinburgh on July 22 after a very brief illness. He was 60 years of age. He was a native of Kelso and was educated there and later at George Watson's College, Edinburgh. He studied medicine at the University of Edinburgh, and graduated M.B. Ch.B. in 1909. His interests lay in the laboratory side of medicine, especially in pathology and bacteriology, and he was for a time assistant in pathology with Professor J. Lorrain Smith. In 1913 he gained his MD (with high commendation) and about this period studied for a time in Paris. During the first world war he served in the R.A.M.C., acting as bacteriologist in East Mudros with the M.E.F., and later being in charge of the laboratory of the 42nd General Hospital at Salonika.

After the war he became bacteriologist to the Royal Infirmary at Edinburgh, a post he held until his death. In 1919 he was elected FRCP Ed, and in 1925 he obtained his DPH. During his long tenure of the position of bacteriologist to the Edinburgh Royal Infirmary, Dr Logan produced a number of useful papers on bacteriological subjects. For many years he was a member of the laboratory committee of the Royal College of Physicians and gave useful advice in his own quiet way. He was a member of the Pathological Society of Great Britain and Ireland, of the Edinburgh Pathological Club and of the British Medical Association. In 1927 he was Vice-President of the Section of Pathology and Bacteriology at the Annual Meeting in Edinburgh of the B.M.A.

Logan was of a quiet retiring nature, never seeking the limelight and shy of voicing his opinion, but always ready to help his colleagues in bacteriological problems. His other interests were gardening and golf which he played well. For a number of years he lived in Colinton where he had a beautiful garden tended largely by himself. It was one of his great regrets that owing to the state of his health in the last year or so he had to give up both his gardening and his golf. Dr Logan leaves a widow to whom deep sympathy will be extended.

Dr HAROLD ERNEST KITCHEN died suddenly on July 4 at the age of 71. A student at Cambridge and St Mary's Hospital, he qualified in 1906.

Dr Kitchen went to the Isle of Man in 1912 settling first in Douglas and later moving to Ramsey, where he remained in practice up to the time of his death. He was elected a member of the Isle of Man Medical Society in 1913 and at once took an active part in its affairs, reading a paper on "Strange Remedies" in that year. During the five years from 1919-24 he was secretary of the society and played a prominent part in

the negotiations over the implementing of the health insurance scheme the introduction of which into the island had been delayed by the war. So much were his efforts appreciated that the society elected him as a director of the Manx Health Society, a post he continued to fill up to the time of his death on July 4, the day before the National Health Service began to operate. Thus, throughout the whole of this long period he upheld the prestige of the profession as the society's representative. He attended the annual representative meeting in the centenary year of the British Medical Association while president of the society, which had in that year amalgamated with the recently created Isle of Man branch of the British Medical Association. Dr Kitchen always took great interest in the work of the branch. Dying as he did in the middle of a urbu meeting of the society, shortly after he had expressed himself in forthright terms, his colleagues have been left with a characteristic picture of Dr Kitchen, ever ready to take up the fight where the honour and well-being of the profession were concerned.

Dr LEIGH RICHMOND HERBERT PETER MARSHALL, who died on July 10, was the only son of the late Dr Henry Marshall, of Clifton Bristol. Before studying medicine at Edinburgh University he spent some years abroad tea planting. He graduated M.B., Ch.B. in 1907 and took his M.D. two years later, being highly commended for his thesis. After graduation he held appointments at the Deaconess Hospital, the Royal Infirmary, Edinburgh, and the Edinburgh City Fever Hospital. Thereafter he settled down in general practice in Peebles and district. At the beginning of the National Health Insurance scheme Dr Marshall, on principle, declined to enter the service. He retained, however, an extensive practice in the surrounding district. For a number of years he was medical officer of the local child-welfare clinic. During the war of 1914-18 he served for three years in East Africa, being twice mentioned in despatches and awarded the O.B.E. for his services. Dr Marshall was a member of the B.M.A. for forty years, and was chairman of the South-Eastern Counties Division in 1931-2. He retired from practice some 12 years ago and resided in Edinburgh to within a few months of his death. During the last war however, he was active in recruitment medical board work and at an A.R.P. first-aid post. He was a keen churchman, and was in particular associated with the executive committee, the Theological College, and the Overseas Mission Board of the Scottish Episcopal Church. The sympathy of all who know her is extended to his widow in her loss.

Dr G. A. Auden writes. In the obituary notice of Dr A. L. S. Tuke (June 19, p. 1212) no mention is made of his services in Gallipoli. At the time of the great blizzard and floods of Nov. 26-7, 1915, the Fife and Forfar Yeomanry were in the trenches. The official history of the campaign gives the number of casualties as 189 men drowned or dead from exposure and some 8,000 evacuated for frost-bite. There was necessarily much confusion, but Tuke worked all night and the following day in collecting the casualties and passing them on to the field ambulances. I have vivid recollections of seeing him on the 27th, cheerful and imperturbable, and quite indifferent to his own physical hardships. This notable service should be placed on record.

## Medico-Legal

### DAMAGES FOR LOSS OF SENSE OF SMELL

[FROM OUR MEDICO LEGAL CORRESPONDENT]

The chief clerk of the Cambridge regional petroleum office was thrown from an Eastern Counties bus (in the days when buses were run by companies) through the negligence of one of the company's servants, and his skull was fractured. When he recovered his sense of smell was gone for ever. Mr Justice Croom-Johnson awarded him £750 damages, remarking that for a gardener of 58 to be unable to enjoy the perfume of the flowers he grows is a serious affliction. Some readers may be more impressed by the handicap the patient himself mentioned in evidence, that he could not now distinguish between the smoke of a cigar and that of a cigarette. Few of us nowadays get the chance to do anything of the sort, but to be deprived of the joy of smoking even cigarettes may for some be more grievous than to be unable to smell a rose.

## Universities and Colleges

### UNIVERSITY OF OXFORD

Arthur Duncan Gardner, D.M., F.R.C.S., has been appointed Regius Professor of Medicine in succession to Arthur William Mickle Ellis O.B.E., D.M., F.R.C.P., who has retired.

### UNIVERSITY OF CAMBRIDGE

On July 26 the honorary degree of D.L. was conferred on Thomas Benjamin Davie, M.D., F.R.C.P., Principal and Vice Chancellor of the University of Capetown.

### QUEEN'S UNIVERSITY, BELFAST

The following medical degrees were conferred at the summer graduation on July 9.

M.D.—W. M. Brown, M. W. Johnstone, M. Maureen E. McNeill, M. W. J. Boyd, W. L. Burrowes, H. Donnelly, Elisabeth Elliott, Linde E. U. Ewald, W. A. Kennedy, B. E. McConnell, J. McConnell, T. R. Malloy, J. H. McK. Pinkerton, D. Rooney, C. D. Ross, J. Schragr, R. G. Vine, E. L. Wilson. M.Ch.—J. T. Shepherd (awarded gold medal). M.B. B.Ch. B.A.O.—J. W. Barr, T. M. Carey, J. A. Cornett, D. Davies, D. F. Donaghy, D. D. Ellis, F. W. M. Emery, W. E. Flewett, J. Gallagher, M. P. Gilmore, T. L. Gracey, J. Henry, Anna F. S. Johnston, G. A. Kernohan, G. Lynch, P. C. McCrea, S. C. Cullough, W. M. M. McGimpsey, B. W. McKinley, F. V. Macaulay, Esmee D. Martin, Phyllis A. E. Meeke, J. D. Montgomery, W. F. K. Morrow, P. O'Connell, W. T. Orton, Eileen D. M. H. Poots, T. P. Sharp, Esther R. Shrage, W. E. Stafford, J. B. Taylor, J. B. Thompson. <sup>1</sup>With commendation. <sup>2</sup>In absentia.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly comitia of the College, held on July 29, with the President, Lord Moran, in the chair, the following Fellows were elected officers for the ensuing year. *Censors*: Donald Hunter, J. Crighton Bramwell, J. F. Smith, R. V. Christie, *Treasurer*: W. G. Barnard, *Registrar*: H. E. A. Boldero, *Harveian Librarian*: Archibald Gilpin, *Assistant Registrar*: W. D. W. Brooks.

Dr Geoffrey Marshall was appointed Harveian Orator and Dr J. G. Scadding Bradshaw Lecturer, both for 1949. The following lecturers were also appointed: Lumleian (1949), Dr A. P. Thomson, Goulstonian (1949), Dr C. Gavey, Oliver-Sharpey (1949), Professor H. P. Himsforth, Charles West (1949), Dr N. B. Capon, F. E. Williams (1949), Dr J. H. Sheldon, Ernestine Henry (1949), Dr Donald Hunter, Croonian (1950), Dr A. E. Clark-Kennedy.

The Registrar announced that the Murehison Scholarship had been awarded to Mary C. Holt, M.B., the Moxon Medal to Dr N. Hamilton Fairley for his contribution to the understanding of the blood pigments and for his work on malaria, and the Weber Parkes Prize to Dr Stephen Roodhouse Gloyne, for his work on the morbid anatomy of pulmonary tuberculosis and its differentiation from diseases due to dust.

Lord Moran was elected the College representative on the governing body of the British Postgraduate Medical Federation and Dr A. E. Naish the College representative on the Court of the University of Sheffield.

The following, having satisfied the Censors' Board, were elected Members of the College.

Z. H. Abdeen, M.B., J. C. L. Adams, M.B., A. K. S. Ahmed, M.B., A. Allison, M.B., R. P. Aronson, M.B., D. V. Bates, M.B., J. M. Beare, M.D., T. P. Blanshard, M.D., A. W. Branwood, M.D., F. S. W. Brumlecombe, M.B., K. P. Brown, M.B., E. Major, R.A.M.C., G. N. Chandler, B.M., M. V. Chari, M.B., E. K. Cruickshank, M.B., Davis, M.B., F./Lt. R.A.F. G. K. Dhariwal, M.B., J. H. Ebbs, M.D. (in absentia), M. M. B. C. D. Garratt, M.B., D. H. Garrow, B. M. B. Helen C. Grant, M.B., G. S. Gray, M.B., T. Hanley, M.B., Audrey Hanson, M.B., J. F. J. Hickey, M.B., C. K. Hurson, L.R.C.P., G. E. Honey, B.M., D. A. Howell, L.R.C.P., P. Jacobs, M.B., L. Jacobson, M.B., B. A. G. Jenkins, M.B., J. H. P. Johnson, M.B., J. G. P. Jones, M.B., R. M. Kamel Refai, D.M., J. A. Keeling, M.B., S. E. Keidan, M.B., W. L. R. Kenyon, M.B., I. Kessel, M.B., J. A. Kilpatrick, M.D., S. G. E. Laverty, M.B., C. W. Lawson, M.B., Theresa Lazar, M.B., R. F. L. Logan, M.D., S. L. Lopus, M.D., E. M. Lourie, M.B., J. MacW. MacGregor, M.R.C.P.E., A. G. McManis, M.B., W. B. D. Maile, M.D., B. M. Mandelbrote, M.B., J. Marshall, M.B., M. M. Martin, M.B., R. Martlew, M.B., W. J. Matheson, M.B., Edith M. Metcalfe, M.B., R. G. Miller, M.B., G. Monckton, M.B., P. D. Moss, M.B., R. Mulcahy, M.B., L. A. M. B. Musso, M.B., T. E. Oppé, M.B., J. S. Pegum, M.B., J. S. Prichard, M.C., M.B., A. W. S. Ritchie, M.B., W. Robinson, M.C., M.D., W. J. B. Rogers, M.B., A. Rusell, O.B.E., M.B., J. B. G. Russell, M.B., A. Z. Shafie, M.B., R. A. Shanks, M.B., N. Shapiro, M.B., D. Sheehan, M.D., J. P. Shillingford, M.D., W. Sreus, M.B., T. G. Smilie, M.B., F. R. Staub, M.D., P. V. Suckling, M.B., J. M. Swinbank, M.D., Mary Townsend, M.B., L. H. Truelove, B.M., D. H. Turnbull, M.B., S. Vaisrub, M.D., D. D. Vora, M.D., Betty Walker, M.B., J. B. Walter, M.B., G. M. Watson, M.B., J. M. Watt, M.B., G. H. Wattlely, M.B., R. Wigglesworth, M.B., O. G. Williams, M.B., R. B. N. Wilsdon, M.B., S. R. Wood, M.B.

Licences to practise were conferred upon the following 149 candidates (including 25 women) who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and who have complied with the necessary by-laws.

C. P. T. Alexander, M. J. Allwood, W. B. Ashby, R. H. R. Aston, P. M. A. Avis, J. C. Barker, M. D. Begley, J. R. Bennett, S. Y. Bhargwa, J. M. Bishop.

The Efficiency Decoration of the Territorial Army has been conferred upon Majors (Hon Lieutenant-Colone's) J L Orr, R Ropner and R J Watson, MC (T.A.R.O.), and on Majors W H Dowell and M L Formby.

## Medical Notes in Parliament

### Poisons Rules

Mr E P SMITH on July 29 again moved a motion for the annulment of the Poisons (Amendment) (No 2) Rules, 1948. The same motion had been counted out on July 26. Mr Smith said that, apart from women, the worst poisoners had all been male doctors. He questioned the adequacy of the safeguards in paragraph 2 of the order, which authorized the supply without a prescription of poison to a duly qualified medical practitioner who in an emergency was unable to furnish a prescription immediately. A prescription in writing must follow within 24 hours. Mr Smith read extracts from a memorandum submitted by the Home Office to the Select Committee on Statutory Rules and Orders. This memorandum referred to a disagreement between doctors and chemists on the practice of telephoning prescriptions, the doctors wanting some relaxation and the chemists being opposed to it. The Poisons Board at first came down on the side of the chemists, but in 1947 recommended the adoption of a draft rule allowing prescribing by telephone. The Home Office referred the matter back to the Poisons Board in consequence of the growing number of deaths from barbiturate poisoning. Eventually the Board's recommendation in a modified form had been embodied in the proposal. At the same time restrictions on the sale of Fourth Schedule poisons were increased.

Mr YOUNGER, replying for the Home Office, said the part of the Order questioned by Mr Smith referred to Fourth Schedule poisons. Mr Younger had no information to suggest that these had recently been used by poisoners or that poisoners had attempted to get hold of them. These poisons were required for medical treatment, and the Home Office had to take account of the legitimate needs of doctors and hospitals. The Poisons Board and the Home Secretary had considerably tightened the rules on the repetition of prescriptions and thereby reduced the facilities for people to obtain these drugs. At the same time one small relaxation had been made to meet legitimate cases of emergency. This relaxation had a parallel in the existing rules dealing with the more dangerous poisons under the First Schedule. In that case the rule had worked well. The Home Office had to depend on the common sense of the pharmacists. If they were not sensible or became corrupt the whole control broke down. There was reason to suppose that where the drug was urgently needed and it was impossible to get the prescriptions provided in advance there had been collusion between the doctor, the pharmacist, and the patient to provide that prescription. It was not good to bring the law into disrepute by retaining this restriction. It was unlikely that any pharmacist called to supply a drug in this way without a prescription would supply sufficient for a fatal dose.

Mr Smith withdrew his motion.

### Acts

Before Parliament adjourned for the Summer Recess on July 30 the Royal Assent was signified to the Criminal Justice Act, Factories Act, National Insurance (Industrial Injuries) Act, Nurseries and Child Minders (Regulations) Act, Statute Law Revision Act, and the Veterinary Surgeons Act.

**Women Medical Students**—Approximately 2,875 women medical students, representing about 27% of the total, are now attending medical schools in Great Britain. There are no schools without women students.

**Report on Midwifery**—The Minister of Health hopes to receive the report of the working party on midwifery in September.

**Deaf aids**—Up to July 26 1,680 Medresco deaf-aids had been delivered from the manufacturers, and 1,200 had been issued to hospitals in England and Wales.

The first issue of an international journal of comparative physiology and oecology, *Physiologia Comparata et Oecologia* has recently been published at The Hague. It has an international board of editors, and it is intended to publish the results of investigations in the fields of comparative physiology and oecology of vertebrates and invertebrates. Articles may be submitted in English, French, or German, those written in French must have an additional summary in English, those written in English or German an additional summary in French. The first number contains among other papers a description of an x-ray study of the intestinal movements of the hen and some observations on the breeding of hares in captivity. *Physiologia Comparata et Oecologia* is a well produced journal, the paper and printing are both good. Britain is represented on the editorial board by C F A Pantin, of Cambridge, and C M Yonge, of Glasgow.

## Medical News

### Honour for Belfast Hospital

His Majesty the King has commanded that the Belfast Hospital for Sick Children shall be known as the Royal Belfast Hospital for Sick Children. The hospital was founded in King Street in 1873, and six years later it was removed to the Old Queen Street Hospital. The present building was opened in 1932.

### Memorial to the late Dr J W Hunter

On July 28 two memorial plaques to the late Dr John William Hunter, medical officer of health and school and port medical officer at Ipswich, who died on August 26, 1947, were unveiled at the Borough General Hospital by his two sons. An obituary notice of Dr Hunter was published in the *Journal* of September 20, 1947 (p 471).

### The Medical Directory

The publishers of the *Medical Directory* (Messrs J and A Churchill, Ltd, 104, Gloucester Place, London, W 1) will be glad to send their schedule asking for particulars, on which they rely to maintain the accuracy of the volume, to any member of the medical profession who has not received one or who has mislaid it.

### Freedom of the Press

The Central London Branch of the National Union of Journalists has adopted a resolution protesting strongly against the threat to the freedom of the Press contained in the recommendation of the British Medical Association on June 29, 1948, that

"Because of the dangers of imitative suicide all inquests shall be held in public but in an inquest on a suicide the Press be prohibited from publishing an account of the proceedings and permitted only to publish that an inquest had been held, the name and address of the deceased and a verdict that the deceased died by his own hand."

### Streptomycin Treatment in Scotland

Arrangements have now been completed by Regional Hospital Boards in Scotland for the extension of hospital facilities for the streptomycin treatment of persons suffering from tuberculous meningitis and acute military tuberculosis. Beds for this purpose have been set aside in selected hospitals in each region and streptomycin is being supplied by the Department of Health for Scotland. Medical practitioners seeking admission for patients suffering from these conditions should apply direct to the nearest treatment centre or to the offices of the appropriate Regional Hospital Board. In the Glasgow area admission can be arranged by telephone application to Glasgow Central 9600. The hospitals in Scotland where this treatment can be given are: Western Region: Ruchill Hospital, Glasgow; Belvidere Hospital, Glasgow; Robroyston Hospital, Glasgow; Mearnsburn Hospital, Newton Mearns; Knightswood Hospital, Glasgow; Royal Hospital for Sick Children, Glasgow; Motherwell Infectious Diseases Hospital, Motherwell; Hairmyres Hospital, East Kilbride; Stonehouse Hospital, Paisley; Infectious Diseases Hospital, Gateside Hospital, Central Hospital, Ayrshire; Falkirk Royal Infirmary, Falkirk; Lochmaben Sanatorium, South-Eastern Region; Bangour Hospital, West Lothian; Southfield Sanatorium, Liberton, Edinburgh; and Cameron Hospital, Fife, will be able to accept cases in the near future. Eastern Region: King's Cross Hospital, Dundee; North Eastern Region: City Hospital, Aberdeen; Northern Region: Culduthel Infectious Diseases Hospital, Inverness.

### Streptomycin Regulations

Regulations (the Streptomycin Regulations, 1948) have been made by the Minister of Health, the Secretary of State for Scotland, and the Minister of Health and Local Government for Northern Ireland, after consultation with the Medical Research Council, bringing streptomycin within the scope of the Penicillin Act, 1947. The effect of these regulations which came into force on Aug 1, is that streptomycin and preparations containing streptomycin may be supplied to the public only by or in accordance with the directions of doctors, dentists, or veterinary surgeons, or by registered pharmacists on the prescription of doctors, dentists, or veterinary surgeons, and may be administered only by or in accordance with, the directions of such qualified practitioners. Though supplies of streptomycin have increased, it is still generally available only through the hospital service. The regulations anticipate the time when its use may be extended.

As with penicillin and preparations containing penicillin, pharmacists and authorized sellers of poisons will be able normally to dispense a prescription for streptomycin and preparations containing streptomycin only once and not more than three months after the prescription was given, if, however, the prescription directs that it may be dispensed on a specified number of occasions or at specified intervals in a specified period, it may be dispensed in accordance with that direction.

**Northern Ireland Health Services**

The present address of the Northern Ireland General Health Services Board is 27, Adelaide Street, Belfast

**Professor T Pomfret Kilner**

Professor T Pomfret Kilner, Director of the Nuffield Department of Plastic Surgery, University of Oxford, has been elected an Honorary Fellow of the American Association of Plastic Surgeons

**Standard Sizes for X-ray Films**

The British Standards Institution has recently issued BS 1443, which specifies the size of x ray film and intensifying screens, together with internal sizes of cassettes, adopted for future use. The Standard was prepared at the request of the manufacturers of x ray equipment and accessories, who have had to meet the needs not only of medical and industrial users in this country but were also faced with the necessity of producing equipment adapted for metric sizes for the export trade. The committee charged with this work has found it possible to provide satisfactorily for all uses with a range of ten inch sizes and six metric sizes, and these sixteen sizes will replace more than thirty formerly in use in this country. The Standard specifies minimum and maximum cutting sizes for x ray film and intensifying screens and also provides for a standard minimum size of cassettes. Films and screens of these sizes will be usable in all existing equipment.

**Diphtheria and Vaccination Returns**

The Ministry of Health has notified local authorities of the diphtheria and vaccination returns required after July 5. As at present there will be two forms of return for diphtheria immunization—six monthly and yearly. There will also be an annual return stating the number of persons vaccinated during the year. In addition special reports will be required about individual immunized children who die of diphtheria, and about cases of vaccination associated with generalized vaccinia, post vaccinal encephalomyelitis, and deaths from other complications.

**Wills**

Dr Charles Francis Orr White, of Dial House, New Inn Lane, Burgham, Guildford, left £45,569. Dr Walter Rupert Reynell, of London, W 1, left estate in England valued at £27,911.

**COMING EVENTS****Mental Health Exhibitions**

Throughout the International Congress on Mental Health which is being held in London between August 11 and 21, two exhibitions are on view in connexion with the session on Cultural Activities in Mental Hospitals. These are "Art and Occupational Therapy," at the County Hall, Westminster Bridge SE 1 and "Patients' Libraries and Pictures in Hospitals," at 1, Grosvenor Crescent, S W 1.

**Medical Week in Hungary**

The Hungarian Medical Trade Union is arranging a Medical Week from Sept 4 to 12 as part of the celebrations of the Hungarian War of Liberty in 1848. Information may be obtained from the Centenary Congress Committee, Bokor Janos u 53, Budapest, 8, Hungary.

**Veneral Diseases Congress**

The International Union against Venereal Diseases will celebrate its 25th anniversary at the General Assembly to be held in Copenhagen on September 6-10. The Assembly will consider plans for the international control of venereal disease and human behaviour in relation to its control. Further information may be obtained from Miss Marguerite Troue, Administrative Secretary, Institut Fournier, 25, Boulevard Saint-Jacques, Paris XIV.

**Speech Therapy Conference**

A Conference on Speech Therapy, arranged by the College of Speech Therapists (68, Queen's Gardens, London, W 2), will be held at the Royal Society of Medicine, 1, Wimpole Street, London, W, from Sept 20 to 24, with morning and afternoon sessions every day. Members of the medical profession making contributions to the conference are as follows: Dr Leopold Stern, "The Emotional Background of Stammering", Dr Macdonald Critchley, "Speech Disorders arising from Head Injuries", and Dr Eleanor M Creak, "The Role of Emotional Problems in Producing Disorders of Speech". Prof Henry V Dicks, Prof Geoffrey Jefferson and Dr W Russell Brain will be in the chair at three of the sessions. In the evening of Sept 20 there will be a Government Reception at Lancaster House, St James's, London, S W, the conference dinner

will be held on Sept 21, and in the evenings of Sept 22 and 23 there will be meetings of the conference committee of the College with overseas delegates and representatives to discuss an International Federation of Speech Therapists. Full particulars of the conference may be obtained from the secretary of the College at the above address.

**Sulphur Congress**

An International Sulphur Congress will be held on Sept 13-15, under the presidency of Prof M Loeper, at Cauterets, Hautes Pyrénées. Sulphur in relation to the endocrine glands, rheumatism, nutrition, the liver, etc., will be discussed. Information may be obtained from Docteur Bernard Mothe, Secrétaire Administratif, Président, Directeur Général de l'Union Thermale Pyrénéenne, 12, rue Duplaix, Pau (Basses Pyrénées).

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

† Deaths from measles and scarlet fever for England and Wales London (administrative county) will no longer be published

‡ Includes primary form for England and Wales, London (administrative county) and Northern Ireland

§ The number of deaths from poliomyelitis and polio encephalitis for England and Wales London (administrative county) are combined

|| Includes puerperal fever for England and Wales and Eire

## EPIDEMIOLOGICAL NOTES

## Paratyphoid at Eastbourne

There have been no new cases notified since Thursday, Aug 5. The total number of reported cases was 43 on that date. Investigations into the cause of the outbreak are still proceeding.

## Typhoid in Arab Refugees

According to a report in *The Times* of Aug 9, 49 cases of typhoid have been notified among the 100,000 Arab refugees who are existing in squalor in the hills of central Palestine. The medical officer of health of Ramallah has expressed fear that unless medical help is forthcoming outbreaks of infectious disease among the refugees may cause many deaths.

## Discussion of Table

In *England and Wales* a decrease in the number of notifications of measles 958, whooping-cough 57, and diphtheria 44 was reported, and an increase in notifications of scarlet fever 44 and dysentery 41.

The largest falls in the incidence of measles were Yorkshire West Riding 161 notifications, Essex 115, Yorkshire East Riding 105, Surrey 93, Caernarvon 92, while the only large rise was 61 in Gloucestershire. The fluctuations in the incidence of whooping-cough were increases in Middlesex 53, and Yorkshire West Riding 41, and a decrease of 40 in Cornwall. Only small changes occurred in the local returns of scarlet fever. The chief features of the returns for diphtheria were decreases in Lancashire 12 and Durham 10.

Rises in the notifications of dysentery of 13 and 11 were recorded in the metropolitan boroughs of Hampstead and Kensington respectively. An outbreak of dysentery involving 12 persons was notified in Yorkshire West Riding Bradford CB. The other large return of dysentery was Warwickshire 10 (Warwick RD 6).

The notifications of poliomyelitis numbered 39, the largest weekly total since January. The only county boroughs with more than one case were Birmingham 3 and Cardiff 3. Counties with more than one notification were London 5, Lancashire 4, Surrey 3, Middlesex 3, Hertfordshire 3, Yorkshire West Riding 2, Yorkshire East Riding 2, and Durham 2.

In *Scotland* the chief feature of the returns was an increase of 27 in the notifications of dysentery. This rise was due to an outbreak in the city of Glasgow, where the notifications increased from 9 to 42.

In *Eire* increases were recorded in the returns for scarlet fever 28 and measles 12, while whooping-cough notifications decreased by 18. In Dublin CB the notifications of scarlet fever rose from 23 to 51. The largest returns for measles were Dublin CB 31, Clare, Killrush RD 18, and Galway, Loughrea RD 18.

In *Northern Ireland* a decrease of 25 was recorded in the notifications of measles. Two cases of typhus were notified in the county of Tyrone.

## Week Ending July 31

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,329, whooping cough 3,309, diphtheria 125, measles 8,211, acute pneumonia 355, cerebrospinal fever 40, acute poliomyelitis 38, dysentery 77, paratyphoid 35, and typhoid 9.

The Surrey Hospitals Divisional Council held its final meeting at Guildford on July 14. It ceased to exist at the conclusion of the meeting, the work which it had set itself to do since 1941 having been taken over by the Ministry of Health as part of the National Health Services. The council came into existence under the chairmanship of the late Sir Laurence Halsey in May, 1941. It was supported by grants from the Nuffield Provincial Hospitals Trust, the Surrey County Council, the Council of the County Borough of Croydon, the voluntary hospitals of the area, and certain other organizations, and was composed of representatives of those bodies. The main work of the council was the preparation of a plan for co-ordinating hospital services in the area it covered. The plan was prepared and was printed in 1947, and has already proved of assistance to local committees set up under the new organization. At the final meeting a vote of thanks was passed to the chairman of the council and to the chairman of the various committees and sub-committees, and to Mrs Seabrooke, the secretary's clerk. Special reference was made, and a vote of thanks passed, to Major J. S. Knyvett, who had with such conspicuous success acted as secretary to the council during its whole existence.

Where do you find  
athlete's foot?

Despite the implication in the name, athlete's foot is more prevalent amongst the non-players than it is amongst players, to all of whom care of the feet is of primary importance. The introduction of 'Mycil', the new fungicide—*p*-chlorophenyl- $\alpha$ -glycerol ether—developed in the B D H Research Department, has made available to medical men a highly effective

preparation for prevention and treatment of this wide-spread infection. 'Mycil' is available as 'Mycil' Ointment and 'Mycil' Dusting Powder.

ALGINATE WOOL

## The ideal dressings for all burns and wounds

In the treatment of burns and wounds it is essential for the dressing to act as a barrier against reinfection. When treating infected burns and wounds it is essential to incorporate bacteriostatic or bactericidal substances in the dressing. It has been stated both conclusively and authoritatively that the danger period is during the "Change of Dressing" \* CALGITEX ALGINATE GAUZE OR WOOL fulfils all the requirements of the ideal dressing. By being SOLUBLE in physiologically tolerated Alkaline media, they permit the change of dressing to take place without exposure of the raw surface to the potentially microbe-laden atmosphere. They provide the ideal dressing for both CLEAN and INFECTED accidental burns and wounds, also for OPERATION WOUNDS in all branches of Surgery.

The following developments are now available —

### FOR EXTERNAL USE

## CESSANTE CAUSA, CESSAT EFFECTUS (COKE)

*By neutralizing the cause  
you neutralize the effect*

Neutralization of the excess acid in the stomach without impairment of the normal digestive processes is the key to the satisfactory treatment of hyperacidity and peptic ulcer.

'ALUDROX,' a suspension of 5.6% colloidal aluminium hydroxide in gel form, rapidly controls this free acid without interfering with combined acid. A peptic ulcer quickly heals and pain is promptly relieved. The aluminium hydroxide is excreted later unchanged, thus avoiding all risk of alkalosis.

## Any Questions?

*Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.*

### White Children in the Tropics

**Q**—*What are the dangers of life in the Tropics for white children of school age as distinct from adults? Is there any special need for additional supplies of chlorides and vitamins especially the B complex?*

**A**—There are no special dangers in the Tropics for white children of school age as distinct from adults, except in so far as children, owing to lack of experience or judgment, may expose themselves to greater risks of infection, trauma, or exposure, but these additional risks may be minimized by supervision, instruction, and training. There is an increased loss of salt in the sweat and urine under tropical conditions, and it is therefore necessary to ensure an adequate salt intake. This should be within the range of 8 to 15 g daily, according to climatic conditions. If there is any doubt about adequacy of the salt intake the following test should be carried out on a 24-hour specimen of urine. Take 10 drops of urine, add 1 drop of 20% potassium chromate solution, and run in a 2.9% solution of silver nitrate drop by drop shaking after each drop.

Note the number of drops of silver nitrate solution needed to change the colour from yellow to brown, this gives the concentration of salt in grammes per litre of urine. If there is salt deficiency the number of drops will be less than 5. The human requirements of vitamins A and D are not increased by tropical conditions, and there is no reliable evidence that greater amounts of the vitamin-B complex or ascorbic acid are needed. If the child has a good mixed diet, including wholemeal bread, butter, eggs, milk, meat, and green vegetables or fruit, the vitamins will look after themselves.

### Pigmentation and Size of Nipples

**Q**—*A young woman who is to be married in a few months time is unduly worried about the fact that her nipples are diminutive and almost colourless. Would stilboestrol increase the pigmentation and size of the nipples and, if so, in what dosage? Is its use justifiable in a case such as this where the anxiety and worry are real and cannot be allayed by simple reassurance?*

**A**—Yes, stilboestrol would increase the size of the nipples and their pigmentation. The suggested dosage is 2 mg of oestradiol benzoate daily by injection locally for three weeks after the end of each period. The writer thinks its use is justifiable and the results would allay anxiety and worry. Treatment should be effective within a few months, and could then be discontinued. The physiological results of marriage and pregnancy will subsequently be beneficial to the diminutive nipples.

### Sulphathiazole as a Cream Base

**Q**—*Cremor sulphathiazole often contains sulphathiazole incorporated in an emulsion-cream base of the Janette wax type. The preparation is rather gritty owing to the crystalline nature of the sulphathiazole. The question arises whether the use of sodium sulphathiazole would be permissible. Would a better preparation result by dissolving an equivalent amount of this salt in the water used to make the emulsion base? On the other hand would the patient get the full action of sulphathiazole on the skin? A solution of sodium sulphathiazole is strongly alkaline (pH 10) would this affect the tissues or the therapeutic action of the preparation?*

**A**—Sulphathiazole usually occurs as a micro-crystalline compound, and if this were to be incorporated as an ingredient of a cream it would cause the preparation to be somewhat gritty but sulphathiazole itself is also available from a number of sources as a perfectly impalpable powder, and there seems to be no reason why this should not always be used in the preparation of a cream. The writer has used it since its

introduction and has produced a perfectly smooth cream about which no complaint has ever been made. The use of sodium sulphathiazole, because of its alkalinity, is not to be advised.

### "Mapharside" in Syphilis

**Q**—*Is "mapharside" superior to the arsphenamines in the treatment of syphilis with regard to therapeutic efficiency and to avoidance of toxic reactions (jaundice etc)?*

**A**—Opinions differ about whether mapharside is superior to the arsphenamines, especially neoarsphenamine, in the treatment of syphilis. In Great Britain most authorities on the subject favour the latter, but in the U.S.A. "mapharsen" has almost ousted neoarsphenamine. It is probable that there is not much to choose between the two in therapeutic efficiency if mapharside is given twice or three times weekly. As regards toxic reactions mapharside is safer in the dosage usually employed, but this is, in part at any rate, due to the fact that a relatively much smaller dosage is commonly used than is the case with neoarsphenamine. Much of the jaundice that occurred in the last four years, particularly in the Services, was shown to be due to virus infection rather than to arsenic.

### Unpleasant Taste and Hypochlorhydria

**Q**—*A woman aged 35 complains of an unpleasant taste in the mouth. A fractional test meal shows both total and free acid to be very low. Before withdrawing the last sample I gave her a glass of gin and vermouth (a drink which she often takes) with the result that the secretion of acid in the stomach rose to the equivalent of about 50 ml of N/10 sodium hydroxide. Is it likely that the unpleasant taste in the mouth is connected with hypochlorhydria? If so what should one do about it in view of the fractional-test-meal findings?*

**A**—It is highly improbable that the unpleasant taste in the mouth is connected with hypochlorhydria. The only connexion might be that the low acidity may be an indication of the presence of chronic gastritis or carcinoma. Both conditions may give rise to an unpleasant taste resulting from regurgitation of stomach contents. Further investigation is called for with these conditions in mind.

### Air Conditioning

**Q**—*What is meant by 'air conditioning' of buildings? Is there some article or booklet on the subject without too much technical detail?*

**A**—By air conditioning is meant the control of the moisture content, temperature, and purity of the air. It is a "combination of ventilation with heating or cooling." This is a quotation from *Modern Principles of Ventilation and Heating* by T. Bedford (H. K. Lewis, London 1937. Price 4s. 6d.).

### Stilboestrol and Prostatic Hypertrophy

**Q**—*Is the administration of stilboestrol likely to be helpful in ameliorating symptoms due to simple enlargement of the prostate in a man aged 60? If so, what dosage is advised?*

**A**—Stilboestrol has no action on a simple enlargement of the prostate, therefore the question of dosage need not be considered.

### Second Attack of Measles

**Q**—*During the recent epidemic of measles I saw a girl aged 2 who I believe had a second attack of measles. I first saw her in April, when she had a mild attack of what I presumed was measles in the absence of occipital glands etc. When I was called to see the child in June she was very poorly indeed with typical morbilliform eruption and very sore eyes. I do not overlook the possibility of the first attack being rubella but I doubt it. Could it be the measles virus attacking again in a greatly stronger phase after passing through susceptible hosts?*

**A**—While authenticated second attacks of measles are extremely rare, it would be unwise to say that they do not occur, since there are nearly always exceptions to the rule in biological phenomena. However, a child of 2 would be unlikely to escape with a mild first attack in the month of April, when

measles was prevalent, unless some attempt had been made to modify the infection with adult or convalescent serum. And if the first infection was measles a second more severe and more typical attack three months later would be most unlikely. The chances are that the earlier infection was not measles but rubella or some allergic urticaria. The possibility, on the other hand, that a child who has had an attenuated attack of measles as a result of the prophylactic use of serum or gamma globulin may not acquire a complete immunity to measles needs investigation.

#### Effects of Dexedrine

**Q**—A patient who complains that he is tired in the evenings and requires nine hours' sleep is in the habit of taking a tablet of dexedrine twice daily. This greatly increases his sense of well-being and he is able to finish a day's work with less conscious effort. Can you tell me (1) Will dexedrine taken continuously damage the kidneys? (2) Will he become addicted to it? (3) Will it cease to have its present happy effect?

**A**—Any healthy subject is tired in the evenings, and many require nine hours' sleep. Generally speaking it is not wise to take drugs such as dexedrine as a regular practice. This drug raises the blood pressure, and may therefore be harmful. It interferes with the formation of aldehydes in the brain, which is surely an undesirable effect to produce daily. It can certainly lead to addiction, as has been found in a considerable proportion of men in American prisons. Whether its good effect will cease is not known, but so far tolerance has not been described. While the use of dexedrine in normal healthy individuals is justifiable occasionally—for example, when it is necessary to drive a motor car throughout the night—its continuous use in healthy subjects is undesirable. Continuous use should be reserved for psychiatric patients with melancholia or similar conditions.

#### Boy's Activities after Epileptic Fit

**Q**—A boy aged 14 had one epileptic fit while in bed. He is athletic and keen on riding and swimming. To what extent am I justified in restricting his activities after only one fit and how am I to estimate the necessity for a sedative and the quantity to be administered? An aunt suffers from petit mal.

**A**—It would be wise to prohibit the boy from riding, and from swimming except in the company of another who is aware of the risk and is himself a powerful swimmer. Sedatives should certainly be prescribed, and a reasonable initial dose is phenobarbitone  $\frac{1}{2}$  gr (50 mg) daily.

#### Complications of Masturbation

**Q**—A man aged 35 who practises masturbation recently complained of severe occipital headache during the act and said that it took a long time to obtain an emission. Is there any explanation for the headache (blood pressure is 140), and is there any drug which will materially speed up the ejaculation?

**A**—If the headache is directly connected with the habit, it is probably of a psychosomatic type, that is to say, a physical disorder resulting from an emotional cause, acting through the autonomic nervous system. In such a case the emotional cause may be worry due to a mental conflict of which the patient may be quite unaware, such as that arising from a sense of guilt, a feeling of dissatisfaction with an imperfect form of sexual expression, disgust with himself, fear of consequences associated with early threats, a basic feeling of anxiety which may itself in the first place have led the patient to masturbation as a solace, or a feeling of latent rebelliousness of which masturbation may be a manifestation. In such cases of conflict emotions may be aroused but without proper discharge, the result being manifested in the form of a headache. Such occipital headaches were found to be the most common form of "worry" headaches among the shell-shock patients of the 1914-18 war (less so in the last war). This emotional conflict may also be a cause of the unsatisfactory emission, since the latent and perhaps unconscious sense of guilt or fear acts as an inhibition to the full expression of the sexual emotion. One would like to ask for what reason this patient has to resort to this habit rather than finding more natural forms of expression in adult love. Masturbation may itself be a neurosis, and, as in many cases of neurosis, the symptoms complained of may be an expression of the healthy and normal

part of his personality rebelling against the more abnormal expression of his sexual instinct. If such a diagnosis is correct, the use of a drug would not cure it, but a frank talk concerning the reason for the habit and for possible worry about the masturbation itself might be more helpful.

#### Doubtful Cases of Typhoid Fever

**Q**—A man aged 78 suffers from pyrexia has a very toxic appearance and a pleural rub. There is no cough or sputum. Widal reaction was positive to typhoid on the 14th day. A specimen of faeces was negative to typhoid bacillus in the third week and three successive examinations of faeces were negative. He has not previously had an illness suggesting typhoid and has not had any T A B inoculations. Was this a case of typhoid fever?

**A**—It is not stated to which antigens (H or O of *Bact. typhosum* or *Bact. paratyphosum* A or B) and to what titres the patient's serum reacted to give a "positive Widal." Positive Widal reactions in low dilutions of the patient's serum may occur in the absence of enteric infection, and have been reported, for example, in tuberculosis. Successive negative faecal cultures from the third week onwards would not be expected in a case of typhoid fever, particularly if modern selective culture media had been used. Again, a patient aged 78 would probably suffer a severe attack, so that diagnosis could usually be made on clinical symptoms and on the course of the disease. The possibility of some chronic infection or neoplasm in the lung in this case deserves consideration.

#### NOTES AND COMMENTS

**Menière's Syndrome**—Dr A. PINEY (London, W) writes: The answer to the question on the treatment of Menière's syndrome (July 24, p. 235) does not make mention of the great value of 10 gr (0.65 g) of bromide with  $\frac{1}{2}$  gr (8 mg) of pilocarpine nitrate thrice daily. This mixture, which has much the same composition as a pre-war German proprietary medicine the name of which I have forgotten, prevents attacks in a very large proportion of cases, and can be taken for months at a time without ill effect. Restriction of fluids is sometimes necessary in order to increase the efficacy of the medicine.

**Hypertension and Flying**—Air Vice-Marshal Sir ALAN ROOK writes: The answer given to the question about the patient with hypertension flying to Canada (*Journal* July 31 1948, p. 280) requires comment. More information about the patient is a necessity before a decision can be given. Are there any present symptoms? Have there been any symptoms or complications? An altitude of only a few thousand feet throws an added strain on the heart. To the normal heart this is no matter, but to one already under stress, causing symptoms while at ground level, it may be of considerable importance. Has the patient flown before? Is she of nervous temperament and likely to be in a state of constant apprehension while in the air? A sudden spasm of fear, possibly quite unnecessary, will increase the already raised blood pressure, perhaps with disastrous consequences. The question whether the stresses of a sea voyage are greater than those of an air passage or not is debatable but at least there is a doctor on board ship with facilities for dealing with an emergency.

It may well be decided when these points, and many others, are taken into consideration that air travel is the best method, but it is not a question that can be answered cursorily in less than five lines.

**Correction**—In the article entitled "Surgical Anatomy of the Parotid Gland" by Mr. Hamilton Bailey in the *Journal* of July 31 the diagrams of the deep lobe (Figures 4 and 5) have been printed in the wrong order. The diagram of the "Deep lobe Variety A, the 'knob'" (Fig. 4) should have been that which appears as "Deep lobe Variety B, the rabbit warren" (Fig. 5), and vice versa.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 14 1948

## CENTRAL CONSULTANTS AND SPECIALISTS COMMITTEE

### FIRST MEETING

The first meeting of the Central Consultants and Specialists Committee was held at B.M.A. House on July 28. It was attended by some 30 regional representatives from England and Wales (including six observers from Regional Committees not yet fully constituted), six members appointed by the Specialists Subcommittee of the Scottish Committee, two representatives from Northern Ireland, and representatives from certain Standing Committees and Group Committees. Mr A. M. A. Moore was asked to take the chair for the meeting.

#### Suggested Joint Action with Colleges and Corporations

The Secretary (Dr Hill) stated that earlier on the same day an important though informal conference had been held attended by representatives of the Royal Colleges and Corporations and of the B.M.A. A long discussion had taken place on the desirability of having a body capable of expressing to the Minister of Health consultants' views on all questions academic, medico-political, and questions which perhaps were intermediate between the two. It had been decided to set up an exploratory committee under the chairmanship of Sir Lionel Whitby to try to hammer out a scheme of collaboration and division of labour. It was decided, too, to put three propositions to the bodies invited to the Conference, these propositions to be worked out by the exploratory committee. They were as follows:

- (1) That a joint committee of the Royal Colleges, the Royal Scottish Corporations, and the British Medical Association be established to advise the Minister of Health on all matters concerning consultants and specialists.
- (2) That the existing Committee of the Colleges and Corporations and the Central Consultants and Specialists Committee established by the British Medical Association continue in existence to brief the Joint Committee.
- (3) That the Joint Committee be requested to allocate, as soon as practicable, fields in which their constituent bodies are free to take independent action and to deal with Governmental bodies direct.

After discussion the Secretary suggested that without making any decision on the main issue the meeting should appoint representatives to the exploratory committee, should examine the report these representatives brought back, and refer it to the regions before coming to any conclusion. Points to be considered would be the terms of reference of the proposed joint committee and the division of labour as between one side and the other.

This course was agreed to, and those appointed to the exploratory committee were Mr A. M. A. Moore, Mr C. E. Kindersley, and Dr Charles Hill.

#### Rights of Part-time Consultants

Dr Rowland Hill raised the question why part-time consultants were not regarded as transferable officers. He said that some specialists might find their appointments terminated by the Minister. Possibly other appointments which the regional board considered to be of equivalent importance would be offered them, but the ideas of the board and of the consultant himself as to equivalent importance might differ considerably. Consultants should have the same security of tenure or compensation on displacement as general practitioners.

Mr Lawrence Abel said that this was one of the points on which the Negotiating Committee had fought all along the line. In Northern Ireland every consultant was allowed to retain his existing appointment.

A resolution was carried that members of consultant and specialist staffs of hospitals, including special departments of hospitals taken over by the Minister on the appointed day should be given security of tenure in their appointments under the National Health Service and should not be compelled to vacate such appointments without their consent for any reason other than misconduct until the attainment of an agreed upper age limit.

The Chairman in putting the resolution said that the Committee fully realized that in some places changes were inevitable owing to the disappearance of a department or the conversion of a hospital to a different use but in the great mass of hospitals there would be no changes and it was desired to secure the position of the part-time consultants in such hospitals.

#### Interim Terms of Service

The Committee had before it a summary of recent negotiations on terms of service for consultants and specialists. The Chairman said that powerful opposition had been offered to the limitation of the maximum quarterly payment for domiciliary work to 100 guineas. Suggestions had also been made for the definition of the half-day such as would prevent specialists who habitually worked very long half-days from being unfairly treated. Finally the inadequacy of the proposed mileage payments had been stressed.

The Committee endorsed a minute of the recent Representative Meeting that every session attended by a practitioner should be paid for at full rate with no limitation on the number of sessions undertaken.

On the question of the length of the half-day Dr Rowland Hill proposed that a half-day session should not exceed three hours. Dr Cochrane Shanks felt that any limitation would bring about the introduction of clocking-in. Consultants and specialists should be trusted by their institutions to do their work and not be required to account to any authority for the hours they spent in hospital.

Mr E. R. Trizelle said that at Leicester a book had been presented to members of the staff in which they were expected to enter the times of arriving at and leaving hospital. Yet they were doing work they had been doing before July 5 and had been asked to go on as in the past. It had been hinted that this instruction to have a book came from above the level of the regional board though whether that was true or not he could not say. Attendance at the hospital for any committee meeting or even for a meal was duly entered. The practice signified distrust and even engendered a feeling of distrust between colleagues. Members from other areas said that something of the same kind had been brought into force and was resented.

The Secretary said that clearly different methods were obtaining in different regions. The notion of the half-day which grew up during the next few months was extremely important because it would have a great effect on the permanent remuneration. He suggested that information should be collected through the Regional Committees as to the half-day definition which was prevailing in each region and that when these reports were available a small subcommittee should look into them. He added that the Ministry disapproved the practice of clocking-in. The only excuse for some sort of log record would be as a means of obtaining information concerning the work of specialists on the basis of which annual payments might be

calculated—a method of timing which, temporarily adopted, would help to eliminate timing in the future

It was agreed to proceed on the lines the Secretary had suggested, and the following were appointed as a subcommittee to examine the reports from regions when available: Dr Rowland Hill, Dr Cochrane Shanks, Mr Staveley Gough, and Dr Ross Smith

On the question of mileage, Mr Abel protested that 6d a mile was totally inadequate, and that both time and distance should be paid for. Mr Hedley Whyte said that if he was required to go from Newcastle to Berwick for a consultation, the fee being £4 4s, and the mileage payment 6d, the net gain to him, supposing the actual cost to be 1s a mile, would be about £1

The Committee decided to undertake an investigation of exact costs of motor-car travel

Brief consideration was given to the question of maximum fees for pay-beds as set out in the regulations under Sect 5 (2) of the Act. Professor T. H. Oliver expressed the fear that the high cost of pay-beds might be one of the methods of eliminating private practice, and he hoped the Negotiating Committee would pay attention to this

It was decided that this matter should be referred to Regional Committees for their consideration and brought up again

The Committee had sat for 3½ hours, and certain other matters remained on the agenda, including the general consideration of the Specialist Spens Report. It was agreed that this should be the first item on the agenda of the next meeting of the Committee, to be held on Sept 30, and that in the meantime Regional Committees should call meetings of consultants in their areas to brief their representatives on the Central Committee

## THE SCHOOL HEALTH SERVICE EFFECT OF NHS ACT

In circular 179 (dated Aug 4, 1948) the Ministry of Education has notified local education authorities of the changes which will have to be made in the administration of the school medical service as a consequence of the coming into operation of the National Health Service. The routine work of school medical inspection and the ascertainment of handicapped pupils will be continued by education authorities, but it will now be the responsibility of the regional hospital boards to provide the specialist services needed by school-children, and education authorities are asked to make the local needs known to the regional boards. No charge will be made to education authorities for any such services provided. It should be noted that in spite of the foregoing arrangement education authorities are not precluded from directly providing any specialist service which it appears to them desirable to provide

### Ophthalmic Work

Ophthalmic work by specialists will follow the same course as other specialist work, but it will be impossible at present for the hospital and specialist services to provide a general service of refraction. In order that the refraction work and the provision of spectacles by the school health service should be maintained, education authorities are asked to take advantage to the fullest possible extent of the supplementary ophthalmic services under the executive councils. Spectacles for children will be provided free of charge provided the prescription is from a doctor on the ophthalmic list or from a doctor employed directly by the education authority

### Minor Ailments

Minor ailments clinics have proved so successful that the Ministry of Education does not intend to make any change in this work, which will continue to be the responsibility of education authorities. The same applies to speech therapy and child guidance, though in the latter connexion children found to need psychiatric treatment should normally be referred to the clinics which will be provided in due course by the regional hospital boards

The school dental service will remain unaffected, and it will continue to be a responsibility of education authorities to provide a comprehensive dental service for school-children

### Hospital Treatment

The cost of treating school-children in hospital will no longer have to be met by education authorities. It is hoped that hospital management committees will be willing to supply information about children on discharge from hospital for the confidential use of the school medical officer

The regional hospital boards will have no power to provide education for children in hospitals, but the special schools now in existence in hospitals will be continued either by local education authorities or by the voluntary organizations which have previously administered such schools. Co-operation between the regional boards, education authorities, and voluntary organizations will be essential if the much-needed special schools are to be provided within a reasonable time

## GROWING-PAINS IN NHS

Miss Alice Bacon, M.P., in the House of Commons recently accused some doctors in the National Health Service of improper practices, but has declined to meet the B.M.A.'s request for details. In a statement issued to the press on Monday of this week the B.M.A. observes that it is regarded as contrary to the standards of medical practice for doctors to discriminate against particular classes, e.g. to refuse to accept as patients children or old people on the ground that they involve too much work.

The Association's statement corrects some prevailing mis-understandings of the present position. It observes that the basis of family medical practice is free choice. "The country wants free choice, and free choice works both ways." It points out that registration with a doctor is a voluntary act and that private practice by doctors who have joined the Service is fully protected by law. And it points out, too, that every doctor has a right to set a limit to the number of patients he is prepared to accept on his National Health Service List.

## WHITE COATS AND OPERATING GOWNS

Members of the profession in private practice have on a number of occasions expressed their surprise that there should be arrangements for the issue of clothing coupon equivalents to enable them to purchase operating gowns but that no similar concession should exist for those who find white coats more serviceable. The Board of Trade has now agreed that coupon equivalents shall be available, for the purchase of operating gowns or white coats at the discretion of the practitioner, to pathologists and other practitioners in private practice who are engaged to some extent in one or more of the following: obstetrics, the treatment of venereal diseases, operations, necropsies, or dispensing.

Practitioners entering or returning to practice—e.g. from H.M. Forces—will be entitled to a coupon equivalent sufficient for the purchase of six gowns or coats, and those already in practice to a replacement issue of three gowns or coats. Applications from practitioners in England and Wales should be addressed to the Ministry of Health in Scotland to the Department of Health for Scotland, and in Northern Ireland to the Secretary of the British Medical Association, and in each case practitioners should state the category in respect of which the claim is made. The coupon equivalents will be made out for 'operating gowns' or 'industrial coat overalls'.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley

## LOCAL HEALTH AUTHORITY SERVICES

A pleasant gesture has been made by the Middlesex County Council in parting from a large number of the staff of the county medical officer of health who as from the appointed day, have ceased to be officers of the Council and have become officers of the Regional Hospital Boards. The Public Health Committee has asked the Council to place on record its appreciation of the loyal and conscientious service which these officers have at all times rendered to the Council—as also have the public assistance officers transferred to the National Assistance Board—and the ready assistance which has invariably been freely given in dealing with the many problems which have confronted the Public Health Committee during the 18 years of its existence. The thanks are accompanied by an expression of the hope that these members of the staff will find every happiness in their new sphere of work, and that by their efforts the great step forward which has been taken in the administration of the hospital services of the country will, with the same loyal and conscientious service, be an immediate and lasting success.

### New Posts for Preventive Medicine

The London County Council, which had already fixed the key positions in the medical and other staff at the central office and the nine divisional health offices under the National Health Service Act, has been considering proposals to give to the key officers the assistance which, so far as can be foreseen at present will be necessary to organize and administer the health services for which the Council is responsible. The estimates of the number of staff required are tentative and will be reviewed after a year's experience. It is considered that positions for two additional senior medical officers should be created at a salary of £1,500 rising by increments of £100 to £1,800. The function of one of these would be to organize preventive and social work against tuberculosis and to co-ordinate the Council's work with the activities of the regional hospital boards and the teaching hospitals. The other officer would be employed in investigating the incidence of epidemics and co-ordinating measures for their prevention and control, and in dealing with the control of infectious diseases in the Council's remaining residential establishments.

Other health services which will need more medical staff are school health, midwifery and maternity and child welfare, and environmental hygiene, for which last a senior assistant medical officer and an assistant medical officer, both part-time, will be employed. It is proposed that the Council shall continue to have the services of Dr A. A. W. Petrie, physician superintendent of Banstead Hospital, as part-time adviser on the Council's duties in relation to mental health after his transfer to the South-West Metropolitan Regional Hospitals Board.

### SUPERANNUATION SCHEME

By amending regulations (S.I. No. 1474) the benefits conferred upon mental health officers are extended to regional psychiatrists employed by regional hospital boards. Employees who undertake national service and who are not superannuable when they left their employment are enabled to become superannuable during their national service if they would have done so had they continued in their employment. The power previously given to local authorities to add years of service, or to convert non-contributing service into contributing service, in the case of such of their superannuable employees as are transferred under the Act to the central health service has been extended to cover their employees who transfer at any time.

Where a person ceases to be employed because of the N.H.S. Act and he did not complete a sufficient number of years' service to entitle him to compensation under regulations made under Section 68 of the Act, he is now entitled to receive the accrued value of his superannuation rights instead of merely a return of the contributions to which he might otherwise be entitled. The class of employment entitling certain mental health officers to reckon part of their service at twice its actual length is extended.

## MEDICAL WAR RELIEF FUND

### EIGHTIETH LIST

#### Individual Contributions

£5 5s—Miss K. McArthur, Harrow (5th donation)  
£2 2s—Dr A. G. F. McArthur, London (6th donation)  
£20 19s—Practitioners in the Island of Man Branch—per Dr C. G. Pantin (amount already sent £267 9s 6d)  
£10 9s—Practitioners in the Worcester and Bromsgrove Division—per Dr R. S. MacArthur  
£5 14s—Practitioners in the Ross and Cromarty Division—per Dr J. R. Anderson (amount already sent £22 7s) Dr L. A. Gillanders, Dr J. Gray

#### Local Medical and Panel Committees

£171 17s 11d—Northumberland (5th donation)  
£43 16s 7d—Ayr County (24th donation)

	£	s	d
Total of above contributions	260	3	6
Total received since issue of second appeal	24,837	11	8
Total since inauguration of Fund	83,491	1	1
Sums for boot's for prisoners of war	216	14	6

As already announced, the Committee of the Fund considers it unnecessary for supporters to send further contributions.

## Correspondence

### Superannuation Scheme

SIR—For weeks I have been watching the *Journal* to see whether someone more competent than I would point out what a raw deal the medical profession is getting over the new superannuation scheme. The District M.O. on a fixed salary always *did* get a raw deal compared with a municipal clerk on a rising salary but this new scheme is even worse. Let us compare the D.M.O. working for 30 years on a fixed salary of £360 + £6 extra fees with the clerk starting aged 20 at 25s a week and rising to £525 a year the last five or six years, retiring at 60. Let us tabulate the figures. Lines 1 and 2 refer to those contributing to the Local Government Superannuation Scheme and lines 3 and 4 to those entering the superannuation scheme for those engaged in the National Health Service.

	Years of Service	Total Earnings	Average Income	Pension
Clerk aged 60	40	£11 000	£275	£350
D.M.O. aged 65	30	£11 000	£366	£183
Doctor A	30	£11 000	£366	£165
Doctor B aged 65	40	£22 000	£550	£330

The first and fourth lines show that the doctor working the same number of years as the clerk, earning double the money, retiring five years older is going to get a smaller pension. Granted there may be other benefits, but the clerk will have paid £550 for his pension and the doctor (line 4) £1,320 for a smaller one. What a scheme!—I am, etc.,

Lines

G. D. SUMMERS

\*\* The "other benefits" available under the new scheme include a lump sum retiring allowance (in the case of Dr B this would be £990 if single, or £330 if married), injury pension, widow's pension, short service gratuity, and death gratuity—ED, B.M.J.

### Mileage Fund

SIR—I read the report of the discussion (*Supplement* July 3, p. 5) on the mileage fund at the Annual Representative Meeting. The Chairman of Council "hoped that the mileage fund would be adequate." He stated that "to day it was approximately £600,000, and in the proposals under the new Health Service it would be something like £1,300,000—a very substantial increase."

Might I point out that it is estimated under the new scheme that for every insured person on a doctor's list there will be 2½ after the commencement of the new Service. Therefore if the mileage is to be even at the same level, the old figure should also be multiplied by 2½, which gives a sum of £1,350,000—practically the same figure as the Chairman quoted, and not "a very substantial increase."

Where a practitioner has many patients on his list over 10 miles distant, it indicates that part of his practice must lie in a sparsely populated area where the patients are shepherds or crofters residing considerable distances apart. A number of the roads are classified as "third class" or even as "bad roads," and the roads are frequently intersected by gates. I am attending a patient just now where I have to open seven gates, drive my car through, and close seven gates before reaching the cottage, and then repeat the performance of opening and closing these seven gates on my way back to the main road again.

The real rural practitioner must often work longer hours than his town or suburban colleague on account of the hours he spends each day travelling yet the urban practitioner can see very many more patients in the day and have a much larger list. The rural practitioners are not satisfied with the present mileage grants, and are not likely to be satisfied with the grant under the new Service if it is to be practically the same as the Chairman of Council states.

I entirely agree with Dr G O Barber (Mid-Essex), Dr G MacFeat (Council) and Dr T O McDonagh (Perth). The whole mileage fund should be increased and higher mileages—i.e. eight miles and over—substantially stepped up as suggested by Dr MacFeat. Let us have the whole question of rural practitioners' time and the mileage fund put on a proper basis right from the beginning of the new Service and not rely on the pickings from the inducement fund—a fund about the administration of which we know practically nothing—I am, etc.,

Newton Stewart Wigtown

A KELLIE BROOKE

\* \* The Secretary of the Association writes: (1) To double the number of persons in respect of whom mileage is paid is not to double the numbers of miles travelled. Accordingly a doubling of the mileage fund means an increase in the payment per mile actually travelled. (2) The Rural Practitioners' Subcommittee is now engaged in preparing a model scheme of distribution which deals with higher mileage and more difficult mileage. (3) Steps are now being taken to divide the special inducement fund between England and Wales and Scotland. When this is done applications will be invited for special inducement grants for consideration by the medical practices committees.

### Future of Assistants

SIR—Now that most of the arguments for or against the National Health Service have been fully dealt with and the midwives of the new Service can rest after the successful birth, is it not time to look more closely into the future of assistants and to rectify the unfairness of their position by withholding from them any practical status in the Act? We are promised that the medical practices committees will soon start combing the districts for finding new openings for the non-established doctors. Meanwhile we also watch the lists of our principals swelling to the most of their capacities while we who did not feel justified after the release from H.M. Forces to buy practices have to hope that, by the time a new opening is found for us, there will be still a few patients free to enter our list, if the neighbouring doctors' lists have already been filled.

The competitive nature of our occupation compels us for the time being to content ourselves with a meagre salary, knowing full well that our work justifies the principals' accepting on their lists an additional 2,500 patients with all the material benefit derived from it. If in the words of the Minister, "it has been vital that the new situation did not carry with it any unfair worsening of a doctor's material livelihood" is it not also vital that something was done about our future now?—I am, etc.,

A DISSATISFIED ASSISTANT

### Medical Records

SIR—How to file the new National Health Service envelopes and record cards is a problem now facing us. Those of us who have made inquiries with a view to purchasing filing drawers or cabinets will have discovered the present high cost of this equipment. The high prices are, I believe, to a large extent due to purchase tax. Why are we being forced to pay out this money now for the various types of filing equipment, which will

sooner or later be of no use to us when the promised centres are built? In my opinion it would have been and farer to all concerned if the Ministry of Health in England and the Department of Health for Scotland had arranged for supply of standard filing units to all general practitioners engaged in the NHS. This equipment when the time came could be transferred for use in the health centres and for the present provided on loan to those G.P.s requiring it at a nominal charge.

If this is asking too much, then surely we should be granted a rebate of purchase tax in view of the fact it is to be used only for keeping records for Government purposes—I am, etc.,

Glasgow

THOMAS A CHRISTIE

### Prescribing in NHS

SIR—In view of the statement made by the Minister of Health in the House of Commons to the effect that there is no limit to the medicine or drugs which a doctor can prescribe to his patients in the NHS, there is an urgent necessity for a radical revision of the panel list of emergency drugs and appliances which has been in force hitherto. Apart from the fact that this list is now very much out of date, it does not cater for all the emergencies confronting a doctor on his daily rounds. Before July 5 the doctor used to resort to drugs which he himself bought for his private patients. When most of one's patients have become panel, this reserve will have gone.

It is therefore clear that if the standard of medical practice is not to sink it is essential that a doctor should be allowed to prescribe for his bag any drugs he may deem necessary. I personally would like to see the following additions to the emergency list: 2 oz 2% solution of gentian violet, 6 oz cod liver oil for burns, a comprehensive range of barbiturates, dihydromorphine hydrochloride and the same with atropine for injection, sulphathiazole, penicillin 100,000 units, for injection, an antihistamine drug, 5-yards roll of "elastoplast" 3 in wide—I am, etc.,

Glasgow

M LICHTENSTEIN

### Remuneration of General Practitioners

SIR—The annotation on the above (July 17 p 143) is of interest to those in towns, but is cold comfort to the country practitioner.

Item 2. He has no surplus of patients on which to train an assistant.

Item 3. Maternity fees (often no electricity and no tap) are not likely to exceed £100.

Items 4 and 5 are not remuneration but merely payment for out-of-pocket expenses, and in the experience of many of us do not cover the cost of drugs let alone the labour of dispensing.

Item 6. To the 60 years old and over the superannuation contribution is merely an imposition.

Item 7. There are no clinics.

Item 8. There is no hospital.

Item 9. Private practice has been virtually killed.

So all that remains is to plead pauper and beg alms under Item 1.

A scheme which through no fault of his increases a man's work and reduces his income by 20% must surely have germinated in a stratum even lower than the subverminous. It is a safe bet that before Christmas many men over the 60 mark will resign and the Minister (and the nation) will be left with an even worse shortage of general practitioners—I am, etc.,

Newton Ferrers Devon

W F BENSTED SMITH

### Remuneration of G.P.s for Hospital Work

SIR—The general practitioners on the staff of the Haywards Heath Hospital (General Practitioners' Hospital) view with grave dissatisfaction the terms offered to them in the recent letter from the Regional Hospitals Board. In this it is stated that a sum of £25 per bed per annum is to be paid into a pool and the proceeds divided according to the wishes of the medical staff of the hospital. This payment is to be made for the care of patients of doctors who are not on the staff and for the treatment of accidents brought to the hospital. Further the letter states that no payment is to be made for the staff attending their own patients in hospital, as this is taken to be included in the remuneration from the local executive council.

In our view the following facts must be considered before the remuneration is accepted. (1) In 1947, 610 major operations were performed in the hospital. This involved the giving of 610 anaesthetics, all of which were administered by the general-practitioner staff. (2) The necessary pre-operative and post-operative treatments were carried out in all these cases. It may be added that many of these cases were night emergencies, and in some cases transfusions were necessary. (3) Treatment of fractures is undertaken at the hospital largely by the general-practitioner staff.

All these duties take up a considerable amount of time estimated to average 10-13 hours per week for each practitioner and are far in excess of the services rendered by general practitioners not on the staff of general-practitioner hospitals. We should be grateful for the views of other practitioners who find themselves in the same position as ourselves—We are, etc

C F J SMITH

Haywards Heath, Sussex

### GP's Doing Obstetrics

SIR—May I, on behalf of Lincoln Local Medical Committee, crave the courtesy of your columns regarding a matter of urgent importance to all practitioners doing obstetrics?

We have been informed that the Sheffield Regional Hospital Board proposes to prohibit general practitioners from conducting cases in the Lincoln City Maternity Home and any other maternity homes taken over by the Ministry of Health. This, in effect, means that the general practitioners will be left only with domiciliary midwifery, while the full-time specialists (not yet appointed) will attend all cases in these nursing-homes and maternity homes under ideal conditions. As these circumstances will no doubt be repeated in many districts, the Lincoln Local Medical Committee would appreciate the views of other interested local medical committees with a view to joint action being taken to counteract this further encroachment on the domain of general practice.

As the columns of the *BMJ* are already overburdened, the best method would be direct communication with the undersigned. Although, at the present stage a sense of frustration pervades the profession, we in Lincoln desire to discourage apathy. Only by concerted and vigorous action now can we protect what little is left of our freedom—I am, etc,

DANIEL ROBERTSON

Secretary

Lincoln Local Medical Committee

The Brooklands  
Swallowbeck, Lincoln

### Rise in Cost of Living

SIR—Esau has sold his birthright: let him see that he gets his mess of pottage. The medical profession, partly because of that apathy which is now so widespread in all sections of the community, partly by reason of a misplaced belief that defence of one's personal rights is somehow out of place and dishonourable, has signed away its freedom. Let us, now that we have agreed upon entering the National Health Service, insist upon full honouring of the Spens Report, which has been accepted by the Minister. This report specifically says that the figures for remuneration are at the 1939 value of money and that they must be adjusted to meet the increased cost of living.

What is the rise in the cost of living? Mr Gavin Martin, of the Confederation of Engineering and Shipbuilding Unions, has recently complained bitterly that skilled workers in these industries are only getting 52% more wages than they did before the war, while the cost of living is 76½% above the pre-war figure. This figure seems to be generally accepted in official circles, as the official cost of living index is so obviously completely misleading.

The cost of living is then over 70% above the pre-war cost. The Spens Report says definitely that the figures recommended must be adjusted to follow the rise in the cost of living since 1939, and this report has been accepted by the Minister of Health. Let us see if its acceptance is being honoured. The report, if I remember correctly, recommended a capitation fee of 15s 6d per head at 1939 values. The Minister is offering us 16s-18s per head at present-day values—a rise of less than 20%.

The specialists' salaries also have been suggested by the Report, and these too are in 1939 values and are also to be adjusted. It now

appears that the Minister is proposing an addition of roughly 20%, an addition which would make a mockery of the whole Report, as it would have the effect of cutting its recommendations by about a third.

It would be interesting to see the Labour reaction if the N.C.B., for example, offered the miners a one-fifth increase on their pre-war wage—and yet the Minister of Health is offering it to the doctors. Are we going to be such apathetic slaves as to accept this treatment? Let us insist, with all the not inconsiderable means at our disposal, upon a full and honest carrying out of recommendations already accepted by the Government. Let us call for a Royal Commission to decide once and for all what is the real rise in the cost of living, and undertake to abide by its judgment. The Minister could hardly do less than agree also. As things are, the Government is using the N.H.S. to destroy the independence and status of a great profession. We, along with other members of the professions, have been told quite candidly by Mr Shinwell that Labour cares neither two hoots nor a tinker's cuss for us—and I for one believe it.

We know our position. We are lost if we are apathetic or indifferent. We must show Mr Bevan that he and his friends cannot ride rough-shod over the professions. Labour seeks only to give fair treatment and justice to its own class. It must learn that the new Britain cannot be built upon this monopoly any more than upon any other monopoly. No country can remain great nor be contented while sectional interests forbid co-operation for the common weal—I am, etc,

Durham

A A REID

### Compulsory Saving

SIR—Is it really of the essence of democracy that a man of nearly 50 years of age may no longer decide for himself whether he wishes to invest in his own senescence or in the education of his children? My eldest daughter has nearly completed her first year at an academy of dramatic art. My eldest son is in his last year at school. If I can find £70 to give him an extra term he stands a very good chance of winning a scholarship at one of our senior universities. Next to him is a boy who wants a career in the Army and is anxious to qualify for Sandhurst. This means another three terms at school, for which I must find some £200. I am perfectly willing, and my wife will gladly share any hardship involved, to make sacrifices in order that these three may achieve their ambitions, but I am officially told that a slab of my earnings is to be taken for a super-annuation scheme for which I have never asked or alternatively that I must more than double my payment of life insurance premiums.

One chases around in an endless cycle of irritation, frustration, irritation, frustration and is then supposed to be able to respond gallantly to glib phrases about "ambitious adventure." We know who is ambitious, and some of us at least, prefer to do our own adventuring in company of our own choosing.

I submit that Mr A Wilfrid Adams must have meant to write "by" rather than "with" in the last paragraph of his letter in the *Journal* of July 17 (p 175)—I am, etc,

Launceston, Cornwall

DONALD M O'CONNOR

### Conditions of Service

SIR—For how long are we to suffer the taunts of the Minister of Health before we dare take some action to redress our wrongs? One week we read that those of us who are not of his political convictions are "less than vermin," and the next week we read that "bovine Anglo-Saxons" could not have had the force of character to launch this new Health Service. Are there not several "less than vermin" and "bovine Anglo-Saxon" members of Council who advised us to enter this Service? I write as a mere general practitioner who has unwillingly accepted the advice of Council and signed into this unhappy Service.

Now that we are all shepherded into the fold, and the gates are closed on private initiative and freedom for ever, let us at least get some sense into our conditions of service, if only by the clarification of some essential points.

1. What compensation are we to get for the use of our homes as consulting-rooms for State patients? The original scheme allowed for health centres for State patients, and it is completely unreasonable to expect the doctor to continue to provide for the upkeep of his surgery and waiting rooms, with their furnishings, light, and heat, without some reimbursement from public funds pending the opening of health centres.

2 What allowance is going to be made the doctor to meet the extra cost of domestic help entailed by the greater influx of patients to the surgeries, resulting in the constant necessity to answer the door bell (for a doctor's house is after all his private home also, and we have not all got homes in which it is convenient to have patients walk straight in)? If the State is going to use my home it should surely provide me with a State paid help to deal with the door telephone calls, and other matters pertaining to a doctor's work, but not his express concern.

3 I received a circular from my local executive council yesterday which informed me that I must purchase my own filing cabinet for documents relating to State patients. They even told me where I can buy it and how much it will cost. What other servant paid by the State has to buy his own filing cabinet for Government forms? Frankly, out of the miserable remuneration we are likely to get, I shall have no loose money to buy filing cabinets, which will doubtless have a purchase tax on them into the bargain.

4 When are we going to get a simple answer to the most important question of all—i.e., the actual pay we are going to receive for the State patients in our medical care? One gathers it is going to be not less than 15s and not more than 18s per head per annum, but nobody seems to know what the exact amount will be. I can think of no other section of the community which has entered into contract to work for the State but has aridly left its income to be discussed after it has started employment. It is just not common sense to do so. *In any event, even at 18s per head it is a miserable reward for assuming responsibility for a human life for twenty four hours a day for a whole year.*

Finally since the *BMJ* has now come down so heavily in favour of this Service which only a few weeks ago it deplored so much please have the sense to cut out this cheap advertisement of the benefits of the Service as evidenced on p 143 of the *BMJ* (July 17) under the heading "Remuneration of General Practitioners." Among other sources of income you draw our attention to the insulting 2s 6d per annum for every 100 persons on the doctors' list. If this is to be one of the sources, then heaven help our gross income! But in any event this could not be reckoned as a source of income by any trick of the imagination since it is merely an amount which is provided by the State for the express purpose of spending immediately on drugs and dressings for emergency use for State patients, and any general practitioner knows that 2s 6d per annum for 100 patients on his list will not by one quarter cover his bills for emergency drugs and dressings.

I have put forward only a few common-sense fundamental points. They are points, however, which call out for early clarification. After the decision of Council in recommending us to accept service in the Scheme we feel that the ground has been swept from under our feet, and that we are bereft of leaders. Will not the Association even at this late hour rouse itself from its lethargy and obtain at least an early clarification of some of these outstanding points?—I am, etc.,

Harrowgate

HARRY R W HAWSON

### Safeguards in the Service

SIR—In reply to Dr G Tayleur Stockings (*Journal* July 17, p 176), who asks what safeguards the BMA has secured against ill-usage, injustice, and tyranny by our employers the British Government, the short realistic answer is *none*. The only protection against ill-usage of the individual is collective action—trade unionism. The BMA is not a trade union and has no legal or effective weapon. If you wish to protect and insure yourself, join the new medical trade union which is inevitable sooner or later. If you refuse to join a trade union, then put up with the ill-usage and don't grumble.

I have been in practice under the old NI Act over 35 years and can assure my younger colleague his fears are very real. I am sending him examples of this privately.—I am, etc.,

Shrewsbury

ALBERT E NICHOLLS

### Holidays in NHS

SIR—Having read most of the correspondence in the *Journal* on the subject of the National Health Service, I have been surprised that I have not yet seen any comment upon what I consider to be a very serious defect in the terms of service. I refer to the subject of holidays. While nowadays it is an accepted condition of almost all employment that employees are given holidays with pay, we in the medical profession, or at any rate those of us in general practice, are required to provide

a deputy in all cases of absence from duty, whether such be due to sickness or recreation, and at our own expense.

I consider this to be a glaring injustice and I am astonished that the Negotiating Committee did not press for a system whereby a locumtenent would be provided at the Ministry of Health's expense (as was done during the postgraduate courses in 1938) for a definite period—say 21 days each year. Since the Government have taken over our practices and we no longer own them, it is up to the Government to look after them when we are away on holiday—or is it considered that doctors ought not to have holidays as other citizens do?

While on the subject of deputies, I do not know of any other section of the community the individuals of which have to pay others to perform their duties when they themselves are absent from work owing to sickness. Is it too much to hope that our leaders will take up this vital matter with the Minister and to persist until they achieve justice for the profession?—I am etc.,

Birmingham

C SPENCER WHITEHOUSE

### Free Choice of Patient

SIR—In the *Daily Telegraph* of July 21, 1948, mention is made of a case in which the London Executive Council has been asking a doctor to give his reasons for not accepting a certain case on his list. Is it not true that a doctor has got a full choice in the selection of his patients? He can accept anyone he likes and refuse anyone he does not like. Why should the doctor be asked by the executive council to give his reasons for not accepting a case? Whatever may be this doctor's personal reasons I strongly believe that the executive council have no right to question him on the matter. If they have, where is the free choice of a patient by a doctor? The Service is only in its third week now and we have lost all our liberties already. What will it be like when it is in full swing?—I am etc.,

Preston Lancs

H C SAKSENA

### Message from the Minister

SIR—Perhaps you were almost bound to print the thing, and it may be churlish to complain, but I think that many readers of the *Journal* will regard "A Message to the Medical Profession" from our Mr Bevan as merely one more, if a minor, irritation. We know that we are supposed to make the best of a rather bad sort of job—a job designed with far too much speed and far too little thought—and I for one do not relish having the matter "rubbed in" by our present Minister of Health, in whom I have hardly any confidence. It is perfectly obvious that the whole scheme should have been postponed until proper clinics had been built and more nurses trained—a fact which will become very obvious during the next twelve months, the only consolation for which may be that we have some other Minister of Health.—I am, etc.,

London W 4

JOHN C C LANGFORD

### Bigotry and Intolerance

SIR—I should like to heartily endorse the letter of Dr S Dillon (July 17, p 176) and to draw the attention of the profession to the systematic campaign of slander directed against us by certain politicians and newspapers during the last two weeks. Barely a fortnight from the inception of the National Health Service we are accused of "sabotaging the Service" and "running a medical black market," apparently for no other reason than that some doctors have exercised the right specifically granted them under the Act—namely, that of being at liberty to accept or decline a particular patient as they think fit. No mention is made of the loyal efforts of doctors to work the Act under the deadening hand of incompetent officialdom, but every trivial incident which can be construed into an attempt to "sabotage" the Service is given the greatest possible publicity, while patients are earnestly exhorted to act as informers and to report every case they can. During the past two weeks I have collected a number of newspaper cuttings and reports on Parliamentary debates which amply bear out the above statement.

The whole thing is sickeningly familiar. No sooner do we give way and agree to surrender our rights under threat of

conomic pressure than the venom and spite of a controlled and servile Press is immediately turned upon us. The timing, technique, and terms used are strikingly reminiscent of those of the late Dr Goebbels and entirely typical of the usages of the totalitarian State. It is a perfect example of that spirit of bigotry and intolerance, so ugly and un-British, which in the last three years has been transplanted on to British soil and developed like a malignant cancerous growth. The object of those behind this campaign is obvious—to prepare the way for demanding more and stricter controls and restrictions on our profession's freedom, so that British medicine will in time be reduced to the same level as German medicine under the Nazi regime.

The slander campaign, of course, is by no means a new thing. For many years the profession has been subjected to a campaign of subtle suggestion and innuendo, encouraged unfortunately by the effusions of certain medical men turned novelists. The general practitioner has been variously represented as Dr Dillon states, either as an ineffectual and obsolescent dodderer or as a racketeering, money-grabbing charlatan, while an ignorant and credulous public has been only too ready to swallow suggestions of this sort.

The result of our lack of spirit and readiness to give in is already becoming only too clear, as is the kind of treatment that we may expect from the exponents of the "lower-than-vermin" school of thought. We are told that the B.M.A. organization includes a well-organized public relations department. If this is so, is it not high time that this department made some sort of effort to justify its existence? In conclusion, I may mention that I have offered to submit the newspaper and other cuttings referred to in this letter to the Association's Public Relations Department for their scrutiny and appropriate action—I am, etc.,

Canford London

G TAYLEUR STOCKINGS

### Compensation for Loss of Goodwill

SIR—It seems to me that the method of calculating annual loss laid down in N.H.S. (Medical Practices Compensation) Regulations, 1948 (No. 1506), Regulation 7 (2) (a), (b), and (c), on the average of the last two years before the appointed day is unfair to ex-Service practitioners and their partners. Most doctors were released in early 1946, in my experience at least a year's work was necessary to work up a practice to its pre-war gross receipts. Hence the gross receipts of the year 1946-7 are considerably less than those of a normal year. The use of a two-year average in calculating annual loss is also at variance with the memorandum 'General Medical Services: Arrangements Concerning General Practitioners,' which "contemplated that the total amount will be divided in proportion to gross incomes in the last convenient accounting year."

I suggest that in the case of ex-Service practitioners practising alone or in partnership, and other practices affected by the war, the average should be of the last year before service and the year 1947-8. Some precedent for this is given by the generous action of the Surrey Panel Committee, which, with the approval of the panel practitioners of the county, paid ex-Service practitioners for 18 months after their return on the basis of their lists at the end of the last quarter before service. Most of us lost financially by our war service, if we gained in more intangible ways. It is unjust that we should lose again—I am, etc.,

West Byfleet Surrey

T T HARDY

\*\* The Secretary of the B.M.A. writes: Exceptional cases, including ex-Service practitioners who have not had time to recover the full value of their goodwill, will be referred to the Practices Compensation Committee (Regulation 9), and this Committee (under Proviso 2 to Regulation 7) will fix what they consider to be a fair assessment.

### Ophthalmic Certificates

SIR—In the past week I have given out over 50 certificates for ophthalmic benefit. The vast majority of these people already wear glasses, and it seems to me utterly nonsensical that our overcrowded surgeries should be cluttered up with people requiring this type of certification. Surely no one wants glasses unless they really need them and equally so the optician is

going to give them only where there is an eye defect. I cannot believe that the Ministry really expects every G.P. to take out a sight-testing chart each time a patient requests this certificate (incidentally without a fee).

It seems to me that this is another of the familiar Ministerial devices of putting obstacles in the way of people, hoping it will deter them from proceeding further in their objective. I should like to ask that the B.M.A. should take energetic action to have this entirely unnecessary certification abolished—I am, etc.

Urmston Lancs

B SANDLER

SIR—I think the "eye certificate" is absurd, and I consider that the B.M.A. should take the matter up at once. First, the certificate says, "I have examined you." What examination is required? Secondly, the word "require" is misused and silly. Thirdly, in common with many G.P.s, I never give a "certificate for eyes" other than a recommendation to consult an ophthalmic surgeon. Fourthly, patients make previous appointments with an ophthalmic optician and then require the doctor "just to sign." I myself have deleted the second line and written in the words "should consult an ophthalmic surgeon." You are not bound to take my advice. This procedure will become tedious. May I ask what is to be done in the case of broken frames and lenses?—I am, etc.

Cricklade Wilts

T R THOMSON

\*\* If a patient breaks his glasses less than two years after his sight was tested he goes to an ophthalmic or dispensing optician to have them repaired; he pays the cost unless he can show that the damage was not caused by his own carelessness. If he breaks them more than two years after his eyes were tested, he has them tested again.—ED. B.M.J.

### Anaesthetists' Fees

SIR—Any attempt to lay down a schedule of medical and surgical fees is bound to result in the creation of a number of anomalies. Many of these are unavoidable and therefore excusable. But when the anomaly amounts to a gross injustice, as is the case with the fees laid down for anaesthetists, a vigorous protest is called for.

Under the proposed scale of anaesthetic fees the maximum fee payable is twelve guineas, the minimum four guineas. Since the majority of operations fall within the intermediate and minor categories it follows that the average anaesthetic fee will be in the region of five guineas.

The administration of an anaesthetic by a competent and responsible anaesthetist entails a preliminary visit to the patient. This visit has usually to be made specially, late in the evening prior to the day of operation. At this visit a careful examination of the patient is made and the relevant history extracted. A suitable sedative and the appropriate premedication are prescribed and a decision come to as to the best anaesthetic technique to be employed for the particular operation and patient. The actual administration of the anaesthetic entails the arrival of the anaesthetist at the operating theatre some twenty minutes before the other members of the surgical team, the transport and supply of heavy and expensive apparatus, the supply of expensive anaesthetic gases and drugs, and the acceptance of a clinical responsibility second only to that of the surgeon, often by a very short head, during the operation. At the conclusion of the operation the patient is conducted, usually carried, back to bed and the necessary resuscitative measures instituted and suitable sedatives ordered. Departure from the building is usually considerably after the other members of the team have left. A post-operative visit is made later in the day, again usually in the late evening, to advise upon any immediate anaesthetic complications and a further visit is made the following day to deal with the less immediate anaesthetic sequelae and to examine the chest. Anaesthetic complications may entail further attendances upon the patient, but in all but frankly minor cases a final visit on the third or fourth post-operative day is customary. For these services, Sir, the anaesthetist is to be rewarded by a fee of the same dimension as that paid to his surgical and medical colleagues for a single consultation. Further comment is, I feel, unnecessary—I am, etc.,

## Association Notices

### MIDDLEMORE PRIZE

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1880 by the late Richard Middlemore, FRCS, of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1949 to the author of the best essay on "The Value of Orthoptics in the Treatment of Squint". Essays submitted in competition must reach the Secretary, British Medical Association, BMA House, Tavistock Square, London, WC1, on or before Dec 31, 1948. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1949.

### SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award.

1 The prize is established by the Council of the British Medical Association for the promotion of systematic observation research, and record in general practice, it includes a money award of the value of 50 guineas.

2 Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3 The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4 Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, WC1, not later than Dec 31, 1948. The prize will be awarded at the Annual General Meeting of the Association to be held in 1949.

5 No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6 If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7 Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

8 The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

9 Inquiries relative to the prize should be addressed to the Secretary.

### KATHERINE BISHOP HARMAN PRIZE

The Council of the BMA is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1949. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949 but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine.

The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, at BMA House, Tavistock Square, London, WC1, not later than Dec 31, 1948.

## H M. Forces Appointments

### ARMY

Colonel C. Scales, MC late RAMC, has retired on retired pay and has been granted the honorary rank of Brigadier.

Colonel H. G. Peake, late RAMC, has retired on retired pay on account of disability.

Colonel W. D. Anderton, MC late RAMC, having attained the age for retirement, is retained on the Active List supernumerary to Establishment.

Lieutenant Colonel R. R. Evans, from RAMC, to be Colonel

LONDON SATURDAY AUGUST 21 1948

## TUBERCLES OF THE CHOROID

BY

RONALD S ILLINGWORTH, MD, FRCP, DPH, DCH

AND

TREVOR WRIGHT, MD, DCH

(From the Department of Child Health, University of Sheffield)

[WITH COLOUR PLATE]

It has long been known that careful examination of the fundus oculi in cases of miliary tuberculosis and tuberculous meningitis may reveal tubercles of the choroid. The concentration of cases of this disease and the prolongation of life which has resulted from streptomycin therapy have provided the opportunity of studying these choroidal lesions and of observing their natural history. In this paper we discuss the frequency with which we were able to find tubercles of the choroid, describe their natural history, and report the findings of similar lesions in cases of tuberculosis in which there was no evidence of miliary spread or of meningitis.

### Historical

It seems that Gueneau de Mussy (1830) was the first to recognize choroidal tubercles in miliary tuberculosis. Jaeger (1855) gave the first anatomical demonstration of these lesions. Manz (1858) described the detailed histology of a choroidal tubercle in a girl aged 15 who died of miliary tuberculosis. Fraenkel (1867) was the first to demonstrate them with the ophthalmoscope, though Von Graefe and Leber (1868) claimed that they were the first to demonstrate them with this instrument. They described the ophthalmoscopic appearance in detail. Cohnheim (1867) gave a detailed description of the necropsy on seven cases, and produced choroidal tubercles experimentally (with miliary tuberculosis) by injecting guinea-pigs with tuberculous material.

Various writers (Fraenkel, 1869, Weiss, 1877, Marple, 1912, Groenouw, 1920, Lotin, 1924) suggest that choroidal tubercles may develop in a few hours. This seems to be extremely unlikely, and the statement is almost certainly accounted for by incomplete initial examination. Bouchut (1869), Fraenkel (1869), and Weiss (1877) emphasized the value in diagnosis of finding choroidal tubercles. Hoeve (1925), Bollack *et al* (1927), Mayrhofer (1935), and Baldenweck *et al* (1938) describe cases in which the diagnosis of miliary tuberculosis was established by finding tubercles of the choroid. The literature was reviewed by Von Graefe and Leber (1868), Weiss (1877), Carpenter and Stephenson (1905), Bredeck (1916), Groenouw (1920), Bollack *et al* (1927) and Paton (1932).

The frequency with which various writers found choroidal tubercles is tabulated below. In many papers it is very difficult to determine whether the cases referred to were meningitis only, miliary tuberculosis only, or a combination of these. The great majority were cases of miliary tuberculosis with or without meningitis. In cases referred

to as meningitis only, the absence of post-mortem evidence that there was no miliary spread makes the accurate designation of these cases impossible for, as mentioned below, careful histological examination not infrequently reveals miliary tuberculosis which on x-ray examination had not been evident.

TABLE I

	No. of Cases	No. of Cases in which Choroidal Tubercles were Found
Koch (1913)	60	8
Koplik (1907)	46	9
Garlick (1879)	26	1
Cohnheim (1867)	18	18
Groenouw (1920)*	225	54
Heinzel (1875)	41	0
Litten (1877)	52	39
Bredeck (1916)	11	2
Tooke (1915-16)	73	7
Moore (1922)	33	10
Carpenter and Stephenson (1905)	42	21
Marple (1912)	13	13
McDermott <i>et al</i> (1947)	13	2
Debré <i>et al</i> (1947)	84	22
Total	737	206 (28%)

\* Quoting Stricker, 1876; Weissenfels, 1881; Bock, 1883; Money, 1883; Neskowic, 1884; Demme, 1888; Rheinhold, 1891; and Gruning, 1901.

A recent textbook (Doggart, 1947) merely states that "choroidal tubercles are visible in many cases of tuberculous meningitis."

### The Clinical Material

Between January, 1947, and May, 1948, 65 cases of miliary tuberculosis and tuberculous meningitis in patients under the age of 14 were admitted to the Children's Hospital, Sheffield. Ten of these cases are excluded from the series to be discussed—four because the fundi were not examined, three on account of some doubt whether or not choroidal tubercles were seen, two because it was impossible to classify the cases owing to lack of x-ray and necropsy examination, and one because pneumococcal meningitis in a case of miliary tuberculosis masked the possible presence of tuberculous meningitis. The difficulty in some of these cases arose because the child was moribund on admission.

By the courtesy of Professor E. J. Wayne and Professor C. H. Stuart Harris we were able to examine the fundi of five unselected adults suffering from miliary tuberculosis or meningitis, and these are included in the series.

Four additional cases of pulmonary tuberculosis in children are discussed because of the finding of choroidal

tubercles without evidence of miliary spread or meningitis. These are not included in the series of 60 cases given in Table II.

### Technique of Examination

It is obvious that the accurate examination of the fundi of infants and small children is a matter of considerable difficulty, and requires much patience and experience. The irritability occasioned by meningitis may make the examination particularly difficult. The pupils in all cases were dilated by 1% homatropine, and a sedative drug such as chloral, 1½ gr (0.1 g) per year of age, was used where necessary. The average time occupied for one examination of the fundi of a small child is about half an hour.

In almost all the children the fundi were examined repeatedly, but in view of the difficulties it is possible that in some cases choroidal tubercles were present but not detected. We feel, however, that in view of the care with which the examinations were carried out the number missed is likely to be small. It is certainly possible that histological examination would reveal tubercles which were too small to be detected by the ophthalmoscope.

TABLE II—Frequency of Choroidal Tubercles in the Series

	No. of Cases	No. of Cases in which Choroidal Tubercles were Found
Miliary tuberculosis	14	7
with meningitis	28	18
Meningitis	18	1
Total	60	26

It will be seen from Table II that choroidal tubercles were found in 25 (60%) out of 42 cases of miliary tuberculosis with or without meningitis, and in only one case of meningitis in which there was no miliary spread. This last case was one of chronic tuberculous caries of the spine with terminal meningitis. Careful histological examination of the organs did not reveal miliary lesions. Of the five adults seen, all suffering from miliary tuberculosis with meningitis, choroidal tubercles were found in three.

That post-mortem examination, especially histological section, is necessary to exclude miliary spread is shown by the fact that in nine of our cases of meningitis in which x-ray examination failed to indicate miliary infection the necropsy revealed miliary lesions in the lungs, in six of these only on histological examination. Our figures for the cases of meningitis without miliary spread may not be quite accurate, as five of the 18 patients are still alive (though two have been observed for more than three months) and in three of the 13 fatal cases no post-mortem examination was possible. Therefore it may be that some of these eight cases should have been included in the group of cases of miliary tuberculosis with meningitis.

It is noteworthy that Sir Frederick Still (1927) said "Tubercles of the choroid are rarely found in tuberculous meningitis if uncomplicated by miliary tuberculosis, whereas they are found in the majority of cases of miliary tuberculosis."

It is interesting that, whereas choroidal tubercles were found in 24 out of 33 cases in which there was x-ray evidence of miliary tuberculosis, they were found in only 1 out of 9 cases in which the miliary lesions in the lung were so small or non-opaque that they could only be discovered at necropsy. The significance of this observation is not clear.

The frequency of choroidal tubercles in the cases of miliary tuberculosis emphasizes the importance and value of a thorough examination of the fundi in all cases of possible miliary tuberculosis or meningitis. In some of the cases

of meningitis in the series the finding of choroidal tubercles enabled a definite diagnosis to be made before an x-ray photograph of the chest was available and before a lumbar puncture had been performed.

In almost all cases the choroidal tubercles were found at the time of the first or second examination. Several writers have suggested that they are found only in the terminal phase of the illness. Our experience does not confirm that suggestion.

In only one case did we observe the appearance of choroidal tubercles during the course of streptomycin treatment. In view of the unsatisfactory response of some cases to streptomycin there seems to be no reason why this should not happen, but it must be remembered that the difficulty of full examination of the fundi of an infant makes it very easy to miss choroidal tubercles at the time of the first one or two examinations. Their discovery may well be explained by an inadequate search previously.

### Description of the Choroidal Tubercle

In the early stage (Plate, Fig 1) the choroidal tubercle appears as a rounded pale-yellow area with a matt surface and an indefinite edge merging into the red background of the choroid. It does not appear to be elevated. There may be only one tubercle, but usually there are several. The largest number observed by us in one eye was ten. The majority are one or two disk-breadths from the disk. The size is usually one-quarter to three-quarters that of the disk, but it is sometimes slightly larger than the disk. It is unconnected with the retinal vessels. It may be traversed by vessels, and if so they are apparently normal.

The histological appearance of the tubercle has been well described by many writers (Manz, 1858; Cohnheim, 1867; Bouchut, 1869; Weiss, 1877; Haab, 1879; Carpenter and Stephenson, 1905; Petrovic, 1926; Bollack *et al*, 1927; Penman and Wolff, 1933; Tooke, 1936; Baldenweck *et al*, 1938). Tooke (1936) draws attention to the absence of involvement of the vaginal space and optic nerve sheath and considers that this is good evidence that choroidal tubercles arise from miliary spread and not by extension from meningitis.

There is swelling of the neighbouring choroid, with destruction of the stroma and infiltration with round cells, endothelial cells, and giant cells. Tubercle bacilli have been found in the lesions in large numbers. The retina is rarely involved, the tubercle being strictly limited to the choroid, but the retina may be thickened and show round cell infiltration (Penman and Wolff, 1933). The retina is often involved by so-called conglomerate tubercle (Groenouw, 1920; Petrovic, 1926; Groenwall, 1933; Balz and Mosto, 1935; Harlowe, 1946).

### The Natural History of the Choroidal Tubercle

We have found very little reference in the literature to changes in the choroidal tubercle. Von Graefe and Leber (1868), Fraenkel (1869), and Groenouw (1920) all mention the increase in size which can be observed by repeated observation. Cohnheim (1867), Von Graefe and Leber (1868), and Fraenkel (1869) describe the paling of the lesion which develops with its increase in size. Marple (1910) shows a good picture of an obviously old tubercle. Barlow (1910) says "Choroidal tubercles may be observed at different stages of development in different parts of the fundus. They begin as minute round dots which gradually become more opaque in their centre." Very little reference has been made to pigmentation. Von Graefe and Leber (1868) mention the occurrence of pigmentation in large tubercles. Debre *et al* (1947) say that "they gradually heal or disappear, leaving residual pigmentation only." They go

n to say that new choroidal tubercles may appear during the course of streptomycin therapy, and may serve as the only indication that all is not well. Lotin (1924) says that pigmentation sometimes occurs in these tubercles and that a chronic course is not uncommon in tubercles of the choroid.

The relative effectiveness of streptomycin treatment has enabled us to observe the changes which occur in choroidal tubercles over a period of several months. We have not seen any tubercles disappear during treatment, and in view of their pathology it would seem unlikely that this would happen. In some cases the tubercles may remain unchanged for some weeks. The possible prognostic significance of the absence of changes in the tubercles is mentioned below.

In at least 20 cases we observed well-defined and definite changes. The area occupied by the tubercle becomes larger and paler and the outline more distinct. Fine dots of pigment appear in and around the pale area (Fig 2). This change is usually noted within eight weeks of starting treatment.

Following this intermediate stage the tubercle becomes paler still, until finally it becomes parchment-white, with a well-defined sharp edge, with heavy black pigment in and particularly around the lesion. There may also be a paling of the red choroid in the area immediately around the tubercle (Figs 3-6). These changes may be complete in 12 to 14 weeks. We think that this parchment-white scar with a well-defined edge and heavy pigmentation may represent the healed tubercle. We have seen incomplete pictures of this several times but the final parchment-white stage in only five cases. One was a case of miliary tuberculosis with meningitis which responded well to four months' streptomycin treatment. The girl had a solitary choroidal tubercle, and we observed in it all the changes from the earliest to the final stage. She is now perfectly well, four months after the cessation of treatment. In another case, discussed below, we noted the same changes occur in a solitary choroidal tubercle in a girl with a tuberculous knee without miliary tuberculosis or meningitis. In another case one choroidal tubercle underwent these changes during the course of four months' streptomycin treatment (Fig 3), while other tubercles, about a dozen in number, never progressed beyond the early intermediate stage. She died. In another case, admitted with a five-months history of miliary tuberculosis, one choroidal tubercle was found in this late stage, while others were found in the early and intermediate stages. The different age of these tubercles may well be due to a continued discharge of tubercle bacilli from the primary focus. In yet another case we observed a choroidal tubercle in the final stage in a child with a primary complex with no evidence of miliary infection or of meningitis. In this case the tubercle had not been observed in the earlier stages. This case is also discussed below.

#### Possible Prognostic Value of Changes in Choroidal Tubercles

We have seen too few cases and observed them for too short a period of time to be able to make any definite statement about the prognostic value of the changes we have described. But it is of note that the three patients whose choroidal tubercles changed to what we consider the final or healed stage, without other tubercles in earlier stages, are clinically well after fairly prolonged observation (all more than seven months), and that of the eight cases in which in spite of prolonged treatment (over three months) the tubercles failed to progress beyond the early intermediate stage death occurred in five and in the remaining three the response to treatment has been unsatisfactory and recovery seems to be very unlikely.

The following are records of two of the cases mentioned above. They illustrate the possible value of the changes described.

*Case 1*—A girl aged 2 years 9 months was admitted with miliary tuberculosis. Four choroidal tubercles were seen in the early stage. She seemed to respond extremely well to streptomycin, and the x-ray picture of the chest became normal. But at the end of four and a half months' treatment, when the question of stopping the drug arose, the choroidal tubercles had not progressed beyond the early intermediate stage. The drug was therefore continued. Meningitis developed, and she died eight months after treatment had been started.

*Case 2*—A boy aged 16 months was admitted with miliary tuberculosis. He seemed to respond very well to streptomycin, and the x-ray picture of the chest became clear, but his solitary choroidal tubercle failed to progress beyond the intermediate stage. Treatment was continued for six months—two months longer than the normal duration of treatment given here—and two months after the treatment was stopped tubercle bacilli were cultured from the gastric washings.

The appearance of a new choroidal tubercle after prolonged streptomycin treatment is naturally of bad prognostic significance. We have seen this happen only once.

*Case 3*—A boy aged 15 months was treated with streptomycin on account of miliary tuberculosis with meningitis. One choroidal tubercle was found when he was first examined. In spite of four months' treatment this tubercle never progressed beyond the intermediate stage, and the radiograph of his chest showed only a partial clearing of the lung field. Five months after the treatment had been started a new choroidal tubercle was discovered. His fundi had been repeatedly and carefully examined, and it seems unlikely that this tubercle had been missed previously. The tubercle, furthermore, is in the early non-pigmented stage.

It is clear that a great deal more work is required on this subject, and we hope to give a further report in due course.

#### Choroidal Tubercles in Other Cases of Tuberculosis

It is generally considered that a tuberculous bacteraemia is a common if not usual sequel of a primary tuberculous infection. It would seem possible that if careful search were made of the fundi of all children with primary tuberculosis an occasional choroidal tubercle would be found.

Randolph and Schmeisser (1915-16) stated that choroidal tubercles could be found, though infrequently, in practically any type of tuberculosis with a primary lesion. Brunthaler (1926) described a boy aged 4 with congenital syphilis and epituberculosis. Multiple choroidal tubercles were found. A year later the boy was in good health, and a few small rounded scars of the choroid were present. Weiss (1877) describes the finding of choroidal tubercles at necropsy in a man in whom no other evidence of tuberculosis could be discovered. Cohnheim (1867) said that choroidal tubercles could occasionally be found in cases of tuberculosis without miliary spread.

We have found choroidal tubercles in four such cases, but in two (thought by the physician and the radiologist to have merely a primary complex) the period of observation has at the time of writing been only a very short one (7 and 19 weeks respectively) and it is too soon to exclude miliary spread.

The two other cases, however, are of special interest, for they have both been observed for nine months and both are clinically and radiologically entirely normal. The following is a summary of these cases.

*Case 4*—A girl aged 4 was first seen with a six-months history of pain in the right knee. Her tuberculin test was positive and a diagnosis of tuberculosis of the knee-joint was made. Three weeks after admission she was found to have a solitary choroidal

tubercle in the early stage. A radiograph of the chest showed a very doubtful generalized mottling of the lung field which the radiologist did not think was that of miliary spread. Tubercle bacilli were cultured from the gastric washings. Further radiographs were taken at intervals, and they have now been normal for four months or more and the child is well. She has not been given streptomycin or other specific therapy. The x-ray photographs are not reproduced in this article, because the mottling was so fine that it would certainly not show in a reproduction, the x-ray picture would probably have been passed as normal unless miliary tuberculosis had been particularly suspected. The interesting feature of this case is that we observed all the changes in the choroidal tubercle which we have seen in the streptomycin cases. The tubercle is now a parchment-white scar with heavy pigmentation around (Fig 4).

**Case 5**—A boy aged 3 was admitted on account of a tuberculous cervical lymph node. He had a history of recurrent cervical abscesses for two years. His tuberculin test was positive. A radiograph of his chest showed a picture identical with that of Case 3, and for the same reason the radiograph is not reproduced here. Tubercle bacilli were cultured from the gastric washings. A month after admission we found what we consider to be the final or healed stage of a choroidal tubercle (Fig 6). The child is now perfectly well, and a radiograph of his chest has been clear for over four months. His choroidal tubercle remains unchanged. He too has had no specific treatment.

It is quite possible that both these cases are in fact examples of chronic miliary tuberculosis undergoing spontaneous cure, but in neither case was it possible to make that diagnosis from the radiograph of the chest.

### Summary

Choroidal tubercles were found in 7 out of 14 cases of miliary tuberculosis without meningitis, and in 18 out of 28 cases of miliary tuberculosis with meningitis. In other words they were found in 25 (60%) out of 42 of all the cases of miliary tuberculosis. They are therefore of great diagnostic value in these cases. They may establish a definite diagnosis before a radiograph of the chest or a lumbar puncture has been performed.

Choroidal tubercles were found in only one out of 18 cases of tuberculous meningitis without miliary spread.

In nine of our cases necropsy revealed miliary tubercles which had not been detected by x-ray photographs of the chest. It is emphasized, therefore, that in a case of tuberculous meningitis miliary spread can be excluded only at necropsy.

In no cases were choroidal tubercles found merely as a terminal phenomenon. They were found at the time of the first or second examination.

The natural history of the choroidal tubercle is described. As time passes the margin of the tubercle becomes more definite, the tubercle enlarges, the centre becomes paler, and the tubercle and the surrounding area become stippled with pigment. In the final stage there is a parchment-white scar with heavy surrounding pigmentation and paling of the near-by choroid.

It is suggested that further observation may well show that the changes described are of prognostic value. Of those cases (eight in number) in which in spite of prolonged streptomycin treatment the tubercles failed to progress beyond the early intermediate stage, death has occurred in five and the remaining three are doing badly. All the cases in which the tubercle progressed to the parchment-white appearance without any tubercles in earlier stages were apparently cured.

Choroidal tubercles were found in four cases of tuberculosis in children in which there was no meningitis or certain evidence of miliary spread. In one of these cases a solitary choroidal tubercle was seen to pass through all the stages described above to the final or healed stage. It seems possible that careful examination of the fundi of all cases of primary tuberculosis will, in some, reveal choroidal tubercles.

Our thanks are due to Professor E. J. Wayne and Professor C. H. Stuart-Harris for allowing us to see their cases, to Drs J. Burke, M. Powell, and J. Briggs for helping in the examination of fundi, to Mr B. Nutt, ophthalmic surgeon, for advice, to Dr J. L. Emery for the histology, and to Dr T. Colver for letting us see his cases. The paintings are by Messrs Hamblin.

## P ROSS OCCUPATIONAL SKIN LESIONS DUE TO PITCH AND TAR

Fig 1—Shagreen skin of forearm A B aged 52. Contact for 26 years. A close up has been taken of the affected part to show the details of the skin degeneration.

Fig 2—Typical pitch wart on upper lip C D aged 50. Contact for 4 years. Dome shaped tumour with keratotic head. Two tiny warts near main lesion. proved innocent at biopsy.

Fig 3—Pitch wart of the scrotum E F aged 41. Contact with pitch and tar for 16 years. Tumour was innocent and disappeared with x-ray treatment.

Fig 4—Epithelioma of scrotum G H aged 42. Contact with pitch and tar for 17 years. Mushroom shaped lesion had been growing for one month and had been mistaken for indolent boil.

Fig 5—Epithelioma of pinna I J aged 39. Contact with pitch and tar for 20 years. He had had the lesion for one month and it was beginning to enlarge rapidly. Note similarity to papilloma in Fig 2.

Fig 6—Epithelioma of upper arm K L aged 49. Contact with pitch and tar for 34 years. Lesion for 5 weeks treated as indolent boil. Note typical epithelioma. Slight break in wall of ulcer marks earlier biopsy. No glands. Healing perfect after.

## OCCUPATIONAL SKIN LESIONS DUE TO PITCH AND TAR

BY

PHILIP ROSS, MD

[WITH COLOUR PLATE]

The terms "pitch" and "tar" refer to a multitude of substances of varying composition and complexity, and a brief study of these compounds is desirable for the better appreciation of some of the problems they produce in industry. In addition to various asphalts and bitumens, Abraham (1945) in his recent treatise describes many types of pitch and tar, their origin and mode of preparation, but from our point of view we need consider only those derived from wood and coal.

*Wood Tars and Pitches*—These are made by distilling various kinds of wood. Typical examples are the Stockholm, Norwegian, and Russian tars, all of which are used in the tarring of ropes, fishing-nets, boats, etc.

*Coal-Tar and Pitch*—The main supply of tar in this country is from the destructive distillation of coal—a process carried out first and foremost in all gas-works, and, secondly, by the big iron and steel manufacturers. In the former instance we have the gas-works tar and in the latter the coke-oven variety. A small amount of blast-furnace tar is formed as a by-product in some of the Scottish iron-works where "splint" coal is used in the extraction of the pure metal from its ore, and an increasing quantity of tar is being made by the low-temperature carbonization of coal.

### Chemistry

As the chemical composition of tar and pitch has a direct bearing on the production of skin lesions it is necessary to consider not only the mode of preparation but also some of the concomitant chemical changes. Tar is made by distilling coal, and pitch is the residue left after the distillation of tar.

*Distillation of Coal*—At the gas-works coal is placed into retorts and heated to a temperature ranging from 1,200° to 1,400° C (Martin, 1917), and, as the coal decomposes, ammonia, steam, coal-gas, and crude tar are evolved, leaving an amorphous mass of coke in the retorts. Similar decomposition occurs when coal is treated in the coke ovens, though the final products may vary somewhat from those produced in the retort houses. In both cases, however, the crude tar is collected for further distillation. In the low-temperature carbonization process the coal is distilled at a reading not exceeding 700° C.

*Distillation of Crude Tar*—This process is carried out either at the gas-works by-products department or at the special tar distilleries. The results of a typical fractional distillation are indicated in Table I, but it must be stressed that the chemicals which are ultimately formed depend on several factors: (a) the type of coal in the original distillation, (b) the exact method of coal treatment—whether by vertical, inclined, or horizontal retort, (c) the temperature and conditions prevailing in the retort itself, and (d) the

actual technique adopted in the tar distillation. The remaining pitch, which represents about a half of the original quantity of tar, is composed of carbon and numerous polycyclic hydrocarbons.

Under normal working conditions tar is a black, heavy, viscous, and tenacious fluid, while pitch is a black, lustrous semi-solid. When subjected to an increasing temperature they become more and more labile, and tar begins to evolve fumes at about 80° C. The pitches fragment easily, and even the "softer" varieties may be ground to a fine dust when cooled to 10° C.

### Industrial Hazards

Because of their unique properties and their cheapness tar and pitch have a widespread application in industry. Hazards from this source occur not only in the gas-works, coke ovens, blast furnaces, and tar distilleries, but also in the manufacture of producer gas, patent fuels, and "briquettes", in asphalt-workers and road-repairers, in the making of certain electrical equipment such as cables, carbon brushes, carbon electrodes and insulations, in the lens industry, where pitch is used to imbed the lenses during polishing, in the building and allied trades, as in the preparation and the handling of roofing felt, special floor materials, paints, and weather-proofing compounds. Seamen and fishermen, too, handle a fair amount of tar and at times show typical lesions.

### Pathology

When we consider the formidable array of coal-tar products, ranging from the light aliphatic and aromatic oils to the complex polycyclic hydrocarbons of pitch, it is not surprising to find that the pathological changes are both varied and bizarre. Our appreciation of these effects is assisted by the knowledge that the heavier oils, tar, and pitch have these characteristics in common: they are all skin irritants, are solvents of lipoids and cholesterol, are auxetic and keratoplastic, and, finally they are carcinogenic. Therefore a skin exposed to these materials may show evidence of epidermal and dermal inflammation, changes associated with an "eczematous" reaction, signs of excessive cell proliferation such as acanthosis, keratosis, and telangiectasis, and perhaps in the later stages malignant degeneration—usually a squamous-celled carcinoma.

An important physical reaction common to many polycyclic hydrocarbons is the property of fluorescence when their extracts are activated by ultra-violet light, and when these solutions are examined spectroscopically one can detect the carcinogens by their typical absorption bands (Mayneord, 1927).

### Clinical Effects

Generally speaking, tar and pitch produce similar skin changes, but differences do occur by virtue of their respective physical and chemical properties. On the one hand, tar contains many light, middle, and heavy oils, while pitch is relatively richer in the polycyclic hydrocarbons. Furthermore, during the processing of pitch a fine dust can be generated with a high power of dissemination and penetration—a circumstance which explains the appearance of lesions (a) in remote parts of the body, and (b) in persons who work in the vicinity of, but not actually in, the particular workshop.

Regarding my own findings, I have been unable to differentiate between the effects of each material, as most of our employees are in contact with both pitch and tar either separately or mixed. Only rarely has it been possible to indict only one compound.

*Tar Burns*—Owing to more thorough mechanization and enhanced methods of protection of the employees severe

TABLE I—Distillation of Crude Coal-Tar

Temperature	Compounds Produced
170° C	Light oils benzol, toluol xylois
170–230° C.	Middle oils phenols, cresols, naphthalene
230–270° C.	Creosote oils tar oils
270–400° C	Anthracene oils
	Residue pitch

Note.—Numerous other compounds are formed in addition to the above aliphatic hydrocarbons, pyridine, anilines, quinolines, sulphur compounds, etc.

tar burns are uncommon in industry. Should, however, the skin receive splashes of hot tar it must be cleansed either by swabbing gently with trichlorethylene or by the use of a special spray containing this solvent. The burn, usually of the second degree, may then be treated in the routine way. The belief that a tar burn could be followed rapidly by an epithelioma (Bang, 1923) is not substantiated by recent observation.

**Tar Erythema**—This reaction is referred to in industry under a variety of names: pitch burn, tar "flashes," and "the smarts." It occurs in those in contact with pitch or tar fumes, and may appear either at the end of the day's work, when the employee emerges into the open, or during the working spell if he is engaged on outdoor duties such as loading or trucking pitch, or tarring roofs. The condition is apparently precipitated by sunlight or a strong wind, and is characterized by severe smarting of the exposed parts of the body, particularly the face and neck. The eyes, too, are often affected, resulting in a burning sensation and photophobia.

Though the symptoms may be sufficiently intolerable to compel the victim to seek refuge indoors, only rarely is he incapacitated for more than a day, and in the majority of cases he is quite able to resume work on the next shift.

In appearance tar erythema resembles ordinary sunburn, and may vary from a slight redness of the skin to a severe dermatitis with oedema. This latter reaction is now uncommon, and is to be seen in those working out of doors in bright sunlight. Of interest, too, is the fact that repeated attacks of this intense form of pitch burn is followed by persistent pigmentation. Conjunctivitis of a varying degree usually accompanies this condition and may necessitate the wearing of dark glasses temporarily.

The causal agent or agents are still unknown, but there appear to be two predominating factors—a sensitization of the skin by some ingredient of the pitch or tar fumes, and the action of bright sunlight on a skin thus rendered susceptible. With regard to the former, the chemicals indicted are thiazine, thiazone, acridine, and other azines present in tar (Leymann, 1930).

To prevent this condition it is necessary not only to apply the general precautionary measures outlined below (under "Prophylaxis") but to use in addition a protective paste or cream which is impervious to tar fumes, pitch dust, and light rays. After experimenting with several applications I have found a kaolin paste based on a formula suggested by Jenkins (personal communication) most efficacious when applied liberally to the exposed parts before each shift (see Appendix).

Treatment of the dermatitis itself should be carried out according to general principles, though I have found that the patients prefer cold cream or similar emollients.

**Allergic Eczematous Dermatitis**—In my experience this reaction has occurred most infrequently. During the past twelve years I have carried out periodic and regular inspections of about 170 employees who handle pitch and tar, and my records show that during that time only six cases occurred, four of which were sufficiently severe to warrant a transfer to alternative work. This may appear somewhat surprising when we consider the virulent effects common to many coal-tar derivatives, such as the phenols, cresols, anilines, nitrotoluene, nitrobenzene, etc.

**Folliculitis, Acne, Comedones**—These phenomena, though quite common among these workers, rarely cause symptoms or disability. The lesions are, in the main, limited to the forearms, face, and neck, and they pursue a chronic course, waxing and waning at intervals. As with ordinary acne, any severe secondary infection may result in the

formation of small pitted scars, many of which can be seen on the faces and necks of some of our older employees. Of interest, too, is the presence in the scrotum and elsewhere of comedones from which one can express a small plug of sebaceous matter, and Henry (1946) has reported the presence of numerous sebaceous cysts in the scrotum of a man working in a low-temperature carbonization plant. These comedones are no doubt due to the mechanical obstruction of the glands by pitch dust.

In the selection of men for this type of work it is best to avoid engaging those who suffer from acne, as their condition is likely to be adversely affected by the materials they handle.

**Pitch and Tar Melanosis**—This form of pigmentation has been recognized in industry for many years. Broadly speaking, there are two main types: (a) a fairly acute form where there is deep tanning of the exposed parts, especially the face, neck, and forearms, and (b) a more chronic variety accompanying other skin changes, such as keratosis and poikiloderma.

The first is a well-known event seen in those who work principally out of doors and who are in contact with pitch or tar fumes. The melanosis usually appears after a few months, is preceded by several bouts of tar "erythema," and persists throughout the summer months, with a tendency to fade during the winter or when the employee is transferred to indoor duties. An interesting concomitant phenomenon is the brown staining of the sclerotics. It is of interest to note also the presence of melanoderma in those in contact with creosote (Prosser White 1934), anthracene (O'Donovan, 1929), and other coal tar derivatives. The incidence of this form of pigmentation has been reduced considerably in recent years by the adoption of the various preventive measures directed against the development of pitch "burn."

The second variety of melanoderma evolves much more slowly and, in my experience, affects first the forearms and later the face, the neck, and occasionally the scrotum. After several years' contact with the materials in question one may perceive one of the following abnormalities: first, a brown mottling of the skin not unlike "freckles"; secondly, a diffuse dusky red pigmentation; and thirdly, a patchy or reticulated deep reddish brown discoloration. The two latter lesions either herald or accompany "shagreen" skin (Fig. 1).

The factors present in the causation of tar "erythema" appear to operate in the production of melanosis, for, according to Foerster and Schwartz (1939), who have carefully studied this latter condition, the tanning is due to the action of certain light rays on a skin made susceptible by the chemical photosensitizers in tar and pitch.

The mechanism of pigmentation has been investigated by Bloch (1927), who asserts that the epidermal dendritic cells of the basal layer of the skin and of the hair follicles (known as melanoblasts) produce the colourless precursor melanogen, which is transmuted into the pigment melanin by the action either of the ferment oxidase or of ultra-violet light. Some authorities believe that the chromatophores which normally carry pigment from the dendritic cells to the blood vessels may themselves generate melanin when affected by tar.

In contrast to this form of pigmentation is the observation of Dr R. E. W. Fisher (personal communication) that tar workers frequently show on their forearms pale areas of skin which are the relics of burns caused by splashes of hot tar.

**"Shagreen" Skin**—This was the name given by Prosser White (1934) to a pathological state of the skin characterized by keratosis, pigmentation, dilatation of the superficial capillaries, and alteration of its texture. It can be caused by the action of a variety of agents such as excessive sunlight, x-rays, and prolonged exposure to oils, pitch, and tar.

and clinically the condition may be regarded as a poikiloderma, several types of which, according to Kinnear (1935), have been described by the following authorities: Jacobi, Petges, Civatte, Riehl, and Hoffmann and Habermann. Only the condition reported by the last two observers had an occupational aetiology. The appearance of "shagreen" skin is unmistakable (Fig 1), and on palpation the integument feels hard, rough, craggy, and inelastic. So far as pitch and tar are concerned one may perceive the inception of this degeneration after about ten years' close contact, when there appear patches of keratosis and scattered areas of telangiectasis on a background of dusky-red pigmentation affecting the forearms. As the condition advances the lesions become more marked and widespread, and involve also the dorsa of the hands, the face, and the neck, until in due course we have the full-fledged "shagreen" skin with pigmentation, telangiectasis, keratoses, areas of epidermal hypertrophy and atrophy, superficial fissuring, and possibly papillomata. Except for occasional irritation or burning sensation, symptoms are absent, and as the changes are permanent treatment is essentially preventive.

### Neoplastic Changes

As has already been indicated, these are manifest as keratoses, papillomata, and epitheliomata.

#### (a) Keratosis

The earliest macroscopic evidence of the auxetic effects of tar or pitch is perhaps to be seen in the stratum corneum, where after several months of exposure one may detect small, raised flattened areas of keratosis ranging from 1 to 5 mm in diameter on the dorsal surfaces of the hands, on the forearms, or on the face. These lesions, which closely resemble flat warts, usually remain unaltered for many years. On rare occasions the hypertrophy can be sufficiently prolific to result in the formation of a cutaneous horn.

#### (b) Papillomata

Papillomatous growths can occur in these workers after one year, though I have seen instances where they have appeared after only six months' contact. Three types have been observed: first, the simple wart, secondly, the typical pitch wart, and thirdly, the soft papilloma. The regions affected are the dorsa of the hands, the forearms, the face, the neck, and the scrotum. Only rarely do we see lesions on other parts of the body.

The *simple wart* resembles the common verruca, and may be sessile or pedunculated. It is innocuous and, as a rule, retrogresses and falls off—the latter process not infrequently being assisted by some minor trauma such as shaving. Should any prove uncomfortable or begin to enlarge rapidly, treatment by low-voltage x rays, by carbon dioxide snow, or by minor surgery should be instituted. Caustics are best avoided in these cases, as their irritant action might stimulate further proliferation.

The *typical pitch wart* appears as a small conical or dome-shaped tumour having a base of apparently normal skin and a keratotic head. The most common site is on the face, particularly near the nostrils (Fig 2), and on palpation one finds the base hard and infiltrated. The lesion should be regarded as precancerous or frankly malignant, and should be treated either by low-voltage x rays or by local excision.

The *soft papillomata* are to be found in those who have been in contact with these substances for several years, and they appear on the face, especially on the eyelids and adjacent regions. They form small, soft, multiple, pedunculated tumours not unlike skin fibromata, and they are quite innocuous.

#### (c) Epitheliomata

Every worker who handles pitch or tar and anyone exposed to pitch dust is liable to become a victim of this hazard. As with the production of experimental cancer in mice there is always a variable latent period between the initial contact with these materials and the appearance of the growth—an interval which in my group of cases has extended from 18 months to 34 years. The occasional and casual handling of the compounds is scarcely sufficient to precipitate neoplasms, but five years' exposure to small amounts of pitch dust has resulted in malignant disease of the skin of the face. The cessation of all handling of these carcinogenic substances does not necessarily render the individual immune from further trouble, as growths have appeared after a "lag" period of many years.

Though pre-existing papules, keratoses, and follicles may suddenly become malignant the majority of these neoplasms are cancerous from the start, beginning usually as a typical pitch wart and enlarging to a diameter of 1/4 in (0.63 cm) or more within two weeks or so. The most common site for their appearance is on the face (Fig 2), in the neighbourhood of the nostrils, but they also occur with some frequency on the dorsa of the hands, the forearms, the nape of the neck, the ears (Fig 5), and the scrotum (Figs 3 and 4). One patient, a man with an industrial history of 28 years' contact with pitch and tar who had advanced "shagreen" skin, suddenly developed four epitheliomata simultaneously—one on the back of the neck, another on the right ear, and one on each forearm.

If left untreated the tumour enlarges and the keratotic head falls off, leaving the classical epitheliomatous ulcer, circular in shape, with a hard infiltrated base, indurated edge, and raw bleeding surface (Fig 6). At first the surface is covered with a tenacious slough giving the lesion the appearance of an indolent boil—an error which, in my experience, has occurred on two or three occasions. At times the base advances rapidly, and by a process of eversion converts the ulcer into a mushroom-shaped mass (Fig 4). The growth is of low malignancy, its spread is slow and localized for quite a considerable time, and glandular involvement is very late. Histological examination reveals a squamous-celled carcinoma, and with early tumours the problem is not so much to find a malignant growth as a cancerous cell.

The best treatment is by the contact low-voltage x-ray apparatus giving about 4,000 to 6,000 r over a period of 8 to 14 days. The epithelioma becomes necrotic, sloughs away, and heals with a thin supple scar which is almost invisible. Early cancers often disappear after a single dose of 1,500 r.

### Pathogenesis of Pitch and Tar Cancer

*The Exciting Cause*—The association between occupation and epithelioma was first recorded by Pott, who in 1775, in his classical description of chimneysweep's cancer (or soot wart) of the scrotum, suggested that the soot (which contains about 40% of tar) was to blame. It was not, however, till the end of the nineteenth century that the lethal effects of pitch and tar were recognized, and in 1907 the definition "scrotal epithelioma occurring in chimneysweeps and epitheliomatous cancer or ulceration of the skin occurring in the handling or use of pitch, tar, and tarry compounds" was added to the Workmen's Compensation Act (Henry, 1946).

Fresh light was thrown on the subject in 1915 when two Japanese research workers produced malignant skin growths in mice by painting their ears with coal-tar, and in 1924 Kennaway proved that a carcinogenic hydrocarbon was present in a fraction of coal-tar which distilled over a

temperature exceeding 500° C. Carrying this investigation further, Cook, Hewett, and Hieger (1933) were able to isolate from two tons of pitch a few grammes of a powerful cancer-producing agent which on spectrum analysis proved to be 3-4 benzpyrene—the now-recognized carcinogen of pitch and tar. In recent years numerous synthetic compounds having a similar action have been prepared—many of them related to the anthracenes (Cook, 1943)—and we now have about 300 such chemicals (Hieger, 1947).

**Relative Potency of the Tars and Pitches**—It would appear, then, that the potency of a tar or pitch depends on the benzpyrene content, and any condition favourable to the appearance of this hydrocarbon would render its action more powerful. Such conditions are (a) the particular type of coal that is mined in Britain and Belgium, (b) the distillation of this mineral at a high temperature, and (c) certain technical factors arising during the treatment both of the coal and of the tar. Generally speaking, gas-works tar and pitch are highly active, blast-works tar is believed to be less noxious, as are the pitch and tar derived from French coal, tar prepared during the low-temperature carbonization process is also relatively harmless, as is the tar obtained from the various woods, coke-oven tar and pitch prepared in America have low lethal effects (Cranch, personal communication), and the bitumens and asphalts, too, have a low carcinogenic action. Some observers, however, regard all types of tar and pitch with suspicion, and in any case from an industrial point of view it is almost impossible at present to obtain in sufficient quantities an inactive tar or pitch. Of the two, pitch is the more conducive to the development of malignant disease.

**Ultra-violet Light**—The skin lesions poikiloderma and epithelioma caused by an excess of ultra-violet light resemble those produced by pitch and tar, but what the relationship is between the light rays and the polycyclic hydrocarbons is unknown. It is of interest to note, however, that the epitheliomata appear far more rapidly in rural districts than in urban—for example, in a country factory the latent period for a skin cancer is from 18 months to five years, whereas in London the analogous interval is from 9 to 34 years. It would appear, then, that an excess of ultra-violet light accelerates the action of the carcinogens in some mysterious way.

**The "Lag" Period, or Delayed Action**—It has long been recognized that a malignant skin growth can appear several years after the individual has ceased all contact with pitch or tar. The longest interval in my series of cases is seven years, but Henry (1946) reports a "lag" period of 51 years in a patent-fuel worker. In what way the cutaneous cells have been "primed" is another puzzle to be solved.

**Susceptibility**—There is no doubt that some workers are highly susceptible to the development of neoplasms of the skin, and this idiosyncrasy does not depend on the colouring alone, as blonds and brunettes are equally liable. Moreover, some employees who have well-marked shagreen skin have apparently never suffered from typical pitch warts, and there are others who have had numerous warts but never an epithelioma. On the other hand, an epithelioma was the first skin lesion (apart from attacks of tar erythema) to appear in seven of my cases. During the past 12 years, from a personnel averaging 170, including 10 women, I have noted skin growths in 102 individuals, and of these 16 showed malignant tumours. Among the women employees who come into contact with these compounds I have observed a corresponding ratio of papillomata but no incidence of malignancy. It is understandable why the exposed parts are affected, but why the scrotum too is involved is not easily explained. Contamination alone is

not the answer, as I have never seen an industrial epithelioma of the penis or of the adjacent parts of the thigh.

### The Increasing Incidence of Occupational Cancer

Since 1920, when epitheliomatous ulceration due to pitch and tar became an industrial disease notifiable to the Chief Inspector of Factories, there has been a steady increase in the number of cases notified. This is clearly shown in Tables II and III, taken from the Annual Report of the Chief Inspector of Factories for the years 1945 and 1946.

TABLE II—Notified Cases of Epitheliomatous Ulceration in Tar Distilling and Gas works 1921-45 (in Five-Yearly Periods)

Period	Tar Distilling	Gas works	Total
1921-5	67 (9)	22 (6)	89 (15)
1926-30	132 (12)	85 (43)	217 (55)
1931-5	178 (11)	88 (51)	266 (62)
1936-40	299 (10)	59 (19)	358 (29)
1941-5	358 (5)	91 (4)	449 (9)

Note.—The principal figures relate to cases; the figures in parentheses to deaths.

TABLE III—Extract from Table I of the Annual Report of the Chief Inspector of Factories for 1946

Industrial Diseases							
Epitheliomatous Ulceration	1920	1930	1940	1943	1944	1945	1946
1 Pitch	32	44 (1)	85 (1)	54	99 (1)	83	98 (3)
2 Tar	10 (1)	53 (9)	34 (3)	57 (1)	61 (2)	93 (1)	103 (4)

It is nevertheless encouraging to observe the decline during the past ten years in the number of deaths recorded, despite the somewhat alarming increase in the numbers notified.

What is the reason for the apparent increase in the incidence of industrial skin cancer? Several factors are involved: first, following the efforts of the Home Office Inspectorate, both the medical world and factory managements have been made aware of this particular hazard and skin epitheliomata which were formerly thought to be a natural visitation are now being considered correctly in the light of occupational environment. Secondly, many workers have now passed the "latent" period and the skins are liable to develop this lesion. Thirdly, because of the increasing interest displayed by surgeons, pathologists and industrial medical officers, many more biopsies are being performed, and tumours which were at one time thought to be innocent are now found to be malignant.

### Prophylaxis

The widespread use of pitch and tar and the dangers attendant on their use render the question of prevention of the utmost importance in industry. This problem can be attacked in several ways.

#### 1 Substitution

As gas-works tar and pitch are carcinogenic, attempts should be made to substitute other less noxious compounds—as, for example, wood tar, bitumen, tar from the low-temperature carbonization process, and fractions from petroleum. Unfortunately the application of these alternative products is not always practicable either because of their unsuitability or because of their prohibitive cost.

#### 2 Protection of the Worker

One of the requirements of the Factories Act is that injurious fumes and dust should be removed by mechanical means, and the strict observance of this regulation would go far in the prevention of skin troubles. Where practicable all the processes should be mechanized to avoid handling of the materials, machines should be enclosed and efficient exhausts should be fitted to carry away any dust or fumes that are generated.

Employees should be made aware of the hazards involved, and be trained to work cleanly and to prevent the dissemination of effluvia. Also they should be encouraged to report early any abnormal skin condition or appearance.

The use of protective clothing, too, is of paramount importance. Overalls made of stout drill material or denim should fit snugly at the neck, wrists, and ankles, and they should be changed and cleaned daily. I would recommend also a daily change of underclothing, but this, unfortunately, is not feasible while clothes rationing remains so severe. The use of "any old suit" which rapidly becomes soiled and impregnated with pitch and tar is to be condemned.

Gauntlet gloves made of stout rubber or leather, when used judiciously in certain processes, have a definite protective value, as have suitable goggles in shielding the eyes.

Employees should be encouraged to maintain a high standard of body cleanliness, and time and facilities should be provided so as to ensure a wash and shower bath after every shift. The application of "barrier creams" and the plentiful supply of warm soft water should obviate the use of special cleansers—either chemical or abrasive—which of themselves may be a fruitful source of dermatitis. The restricted supply of soap is causing concern and the use of substitutes is not always desirable, though "teepol" or similar "wetting" agents may help to eke out the soap ration.

In some firms it has been the custom among those working with pitch, tar, and heavy oils to use soda ash for washing purposes, and some of the older employees are unequivocal in their assertion that the use of this alkali prevented the development of warts. The use of caustic soda has also been referred to by O'Donovan (1929) in the popular treatment of skin growths by men working with tar. Though weak alkali solutions may be beneficial, the use of them cannot be recommended, because of the serious risk of dermatitis.

I am of the opinion that barrier creams fulfil a useful function, and at our works several types are available, depending not only on the materials handled but on personal idiosyncrasy. In addition to the usual properties of a protective cream, the compound should be opaque to ultra-violet light. Several chemical and cosmetic firms now specialize in these preparations and are prepared to make suitable applications, especially if they are supplied with samples of the materials used and provided they are given information about the conditions under which these are handled—for example, the temperature of the process and the use of ancillary substances and solvents. The creams should be applied liberally to the hands, forearms, face, and neck before each working shift.

In a recent investigation by Kennaway (personal communication) it was shown that the use of a protective cream on the skin of a mouse delayed considerably the appearance of experimental tar growths.

### 3 Selection

While it is not yet possible to foretell those likely to develop skin lesions I nevertheless examine all prospective candidates for this type of work, and I exclude those with existing skin disease or with a bad dermatological history. The question of skin colouring is in my opinion not very helpful.

### 4 Inspection

I regard the frequent and regular inspection of employees an important step in prophylaxis. Not only am I able to detect early skin changes of which the worker himself may be unaware, but I am able also to educate and reassure him,

and discuss with him the various precautionary measures that are being adopted. I see almost every pitch and tar worker at three-monthly intervals, and those who have or have had skin lesions are examined as often as their condition warrants. Only in this way can we be sure of instituting early treatment and prevent serious complications.

### 5 Propaganda

Most industrial concerns are loath to broadcast indiscriminately the hazards obtaining in the use of these compounds, and do not favour the distribution of leaflets or the posting of warning notices (except the one recommended by the tar distillers), as these measures are likely to deter men from working in these processes. Instead, individual education and training are left to the medical officer and to the foremen and charge hands. In this way adequate welfare supervision is ensured without creating unnecessary alarm.

### Statistical Surveys

As medical officer to a large engineering firm who manufacture various types of carbon products, I have had during the past 12 years the opportunity of observing some 170 employees who have handled pitch and tar more or less consistently during that period. My investigation has been facilitated by the small labour turnover, for at the end of 1947 there were 87 workers with at least 12 years' service to their credit and 53 with 20 years' or more.

An analysis of the incidence of their lesions is shown in the following tables. In Table IV I have recorded the number of personnel who have shown the appropriate condition for the first time—subsequent recurrences being ignored, and in Table V are noted the latent periods of the various manifestations. Tables VI and VII show the sites of election for papillomata and epitheliomata.

TABLE IV—Incidence of Lesions Among a Personnel (including 10 Women) Averaging 170 from 1936 to 1947 Arranged in Four 3-Yearly Periods Recurrences Not Included

Lesions	1936-8	1939-41	1942-4	1945-7	Total
Allergic dermatitis	2	2	2	0	6
Folliculitis acne, comedones	15	14	21	16	66
Melanosis	10	7	5	3	25
Shagreen skin	17	6	2	1	26
Keratosis	9	8	11	3	31
Papilloma	18	24	40	20	102
Epithelioma	2	2	8	4	16

The following points are worthy of note.

1 *1936 to 1938*—I began my investigations during these years, and while collating the data I encountered conditions which had been in existence for several years. This was particularly the case with the 17 instances of shagreen skin, which had developed several years before 1936.

2 *1942 to 1944*—The increased incidence of folliculitis, keratosis, papillomata, and epitheliomata during this period can be accounted for in two ways. First, the advent of war necessitated an augmented production of accessories derived from pitch and tar, and from 1940 onwards not only were greater amounts of these materials being handled but working hours were extended. Secondly, the establishment of a dispersal factory in a rural area brought a further 20 men into contact with these compounds from the years 1941 and 1942. By taking into account the latent periods one can appreciate the rise in the number of lesions recorded during these years.

3 *1945 to 1947*—I attribute the reduction in skin troubles in this interval to the intensification of the campaign of prophylaxis, especially in the provision of clean overalls daily, in the more widespread use of barrier creams, in the supply of soft water for washing, and in the allowance of ample washing-time. We are indebted to the medical inspectors of factories for their assistance in the clean-overall service and to a firm of cosmetic manufacturers for their research work on suitable creams.

4 *Papillomata*—Of the 102 cases 62 showed multiple warts

5 *Epitheliomata*—16 men developed malignant skin tumours (all confirmed by biopsy), and of these 9 had previously suffered from simple warts and 3 had multiple epitheliomata. There were no fatal cases. The 9 with simple warts have also been included under "papillomata".

TABLE V—*Latent Periods*

Folliculitis acne comedones	1 month or more
Melanosis	6 months to 5 years
Shagreen skin	Over 10 years
Keratosis	6 months or more
Papilloma	6 months to 43 years
Epithelioma { Rural district	18 months to 5 years
{ Urban district	9 to 34 years

Note.—The shorter latent period for the appearance of a skin carcinoma in the rural district is discussed under Ultra violet Light. Because of this latent period all employees who leave the firm are requested (where practicable) to report to us any rash, pimples, or warts that might appear at some future date.

TABLE VI—*Site Incidence Papillomata*

Employees affected	102 (including 6 women)	Age from 29 to 66)
Single lesions	40	
Multiple lesions	62	
Site affected		
Nose and lips	43	
Cheeks eyelids chin	24	
Ears	6	
Neck	8	
Scalp	1	
Hands	29	
Forearms	16	
Scrotum	11	
Leg	1	
Anus	1	
Total	140	

It would appear that the site of election for these growths is the face (48%), the incidence on the hands and forearms is 32%, and on the scrotum 8%.

TABLE VII—*Site Incidence Epitheliomata*

Employees affected	16 (no women)	Age from 34 to 62)
Single lesions	13	
Multiple lesions	3	
Site affected		
Cheeks	5	
Nostrils lips	4	
Ears	3	
Neck	2	
Scalp	1	
Forearms	3	
Arm	1	
Scrotum	4	
Total	23	

The most frequent site for the appearance of epithelioma is on the head and neck regions (65%). The upper limbs and the scrotum each show a rate of 17%.

### Summary

A brief account has been given of the preparation, the chemistry, and the industrial uses of coal-tar and pitch.

The following clinical effects have been described and discussed: tar burns, tar erythema, allergic eczematous dermatitis, folliculitis, acne, and comedones, melanosis, shagreen skin, neoplastic changes, and epitheliomata.

The pathogenesis of pitch and tar cancer has been discussed.

Various prophylactic measures have been described.

A statistical survey has been included.

### APPENDIX

*Formula for Starch and Kaolin Paste for the Prevention of Tar Erythema*

Starch	28 g
Kaolin	1,600 g
Phenol	36 g
Glycerin	50 ml
Distilled water	2 litres

The starch is made into a thin paste with about 50 ml of water and poured into 950 ml of boiling water. The boiling is continued for a few minutes to ensure the breaking up of the starch cells. The phenol and glycerin are added to the mucilage and finally the kaolin, in small quantities at a time, with constant stirring. The final mixing is best done with the hands to make certain that no lumps remain.

The phenol prevents the development of mould in the paste and the glycerin renders the paste more "supple" and prevents rapid drying and cracking. Colouring matter such as cochineal may be added for a better cosmetic effect.

I wish to thank the Controller of H.M. Stationery Office for permission to reproduce the tables from the Annual Reports of the Chief Inspector of Factories, and Professor Kennaway for permission to publish the results of his experiment with a barrier cream in the production of experimental skin cancer (1946). I also wish to express my indebtedness to Mr A. E. Wiggs, B.Sc., Dr. Henry MacCormac, Dr. Davidson, late H.M. Inspector of Factories, and Dr. L. B. Bourne for their kind assistance and suggestions.

## OBSERVATIONS ON TUBERCULOUS MENINGITIS IN CHILDHOOD\*

WITH SPECIAL REFERENCE TO EARLY DIAGNOSIS

BY

W. S. CRAIG, MD, FRCPed, MRCP

Professor of Paediatrics and Child Health, University of Leeds

Of all the clinical pictures met with in children there is probably none which has sustained such intense interest over so many years as that of tuberculous meningitis. The first account of the clinical course of the condition was given over 180 years ago by Robert Whytt during the time that he occupied the chair of medicine at Edinburgh University. His description, under the title "Observations on the Dropsy in the Brain," is still recognized as a classic.

Interest in the subject of tuberculosis in childhood, and of tuberculous meningitis in particular, has received additional stimulus from the trials being given to streptomycin therapy. If this new form of therapy is to receive reasonable trial patients submitted to treatment must be diagnosed early. This constitutes something of a challenge to clinicians, because it must be admitted that we have not advanced greatly from the days of Whytt in the early diagnosis of tuberculous meningitis, no matter how improved are our methods of investigation in relation to the later stages of the condition.

### Successive Clinical Phases

It is customary to describe the clinical course of tuberculous meningitis in terms of three stages. Sir Frederic Still used to say that while no fool could err when the middle and last stage had been reached, the wisest physician might fail to recognize that anything serious was amiss with a child in the first and early stage. It is this early

\*Summary of an address given to the Harrogate Medical Society on Dec. 11, 1947.

stage with which I am concerned, but in order to present things in their proper perspective I will first briefly describe the clinical course of a typical case of tuberculous meningitis in childhood from its insidious onset to its tragic termination

Because I am anxious to lay stress on clinical aspects I propose to consider my subject in the light of what I feel to be the immediate problem faced by the family doctor who has not the advantages of laboratory facilities at his elbow

#### First Stage

This is usually described as the *prodromal or the premonitory stage*. There are many recorded opinions concerning the average length of this period. While most are agreed that it usually lasts for some two to three weeks it has been recognized that it may last for as long as two months. It is generally agreed that there are no absolutely characteristic symptoms during this phase of the disease. Indeed, a disconcerting feature is that not only are symptoms rather vague but they are too apt to resemble those often met with in a number of other conditions. To add to the worry of the clinician, when tuberculous meningitis is suspected at this early stage the problem is not merely one of differential diagnosis as between a number of serious possibilities, but is equally one of deciding whether the symptoms are in fact attributable to a serious or to a comparatively minor condition.

Most of us can remember children whom we have had under observation on account of anorexia, fretfulness, or lassitude, and possibly also failure to gain weight, and who in the course of only a week or two have developed headache and constipation severe and persistent enough seriously to raise the question of meningitis. If vomiting is also present we would instinctively suspect meningitis, but it has to be remembered that cases occur in which the vomiting is so infrequent or is so isolated in character that its significance may not be immediately grasped. Nevertheless I have no hesitation in saying that of the triad vomiting is unquestionably the earliest symptom in the great majority of cases no matter how occasionally it may occur in the individual case. A further point well worth mentioning is that sometimes a child not complaining of headache will complain of pain or perhaps only discomfort in the neck—a symptom never to be lightly ignored.

I like to look upon this stage as one characterized by symptoms which individually appear to have no serious import but collectively reflect considerable and to some extent increasing physical and emotional debility, and concerning which the most striking feature is their persistence.

#### Second Stage

The prodromal stage is usually described as being followed by the *period of irritation* or, as it is sometimes called, the stage of invasion. The transition from one to the other is only gradual. Despite the fact that such suggestive terms as "invasion" and "irritation" are employed, the point to remember is that even in this second stage many of the pronounced signs and symptoms commonly associated with other forms of meningitis are much more likely to be absent than present. This is certainly the case until such time as the stage of irritation is in process of passing over to the third and terminal stage—that of increased intracranial pressure.

In saying this I do not wish to suggest that the clinical picture in the second stage is not often typical to the extent of being almost diagnostic. It is during the second stage that prodromal symptoms lose some of their earlier vagueness and assume more pronounced form. A disgruntled fretful child is seen to become irritable to the point of petulance. Lassitude gradually merges into drowsiness. As drowsiness increases the breathing tends to become irregular, and even before this the child can be heard every now and again—sometimes at long sometimes at short intervals—to give a prolonged, deep sigh. Even at this stage older children may be found up and about in their homes, but more often than not they are curled up in a chair in a shaded corner of the room, their faces turned from the light. If, on the other hand, the child is in bed all the points I have mentioned can be observed without turning down the clothes.

Often the cheeks are slightly flushed although there may be little or no fever. The so-called *tache cérébrale* can be easily obtained. In many cases you will find the child grinding his teeth, sometimes for hours on end. In strange contrast the eyes retain an unnatural brightness.

The moment you draw down the clothes the child shows his resentment. He pushes away the examining hands, clutches at the sheets, protests in a high-pitched voice, firmly closes his eyes, and remains curled up on his side his legs flexed at the hips and knees. The likelihood is that the bones of the thoracic skeleton will be a little prominent, and that the abdomen from being a little full is beginning to show a scaphoid contour. Increasing anaemia becomes apparent. There are periods of great restlessness during which the child picks away at his lips, the umbilicus, or genitalia, and may cry out, not in pain but rather irritably. These periods are only too likely to alternate with times when the patient may sit up and take an interest in his immediate surroundings. Often there is a frown of the forehead, which is the more striking because it is so rare in children. These intermissions of spontaneous interest gradually lessen in length and in frequency as weakness increases.

When you come to examine the child in greater detail the pulse will be found to be slow and possibly irregular until eventually it usually assumes the characteristics of the so-called cerebral pulse. Too much should not be expected from examination of the central nervous system at this stage. It is the exception rather than the rule to elicit Kernig's sign—and although many disagree I find little help from Brudzinski's sign. An extensor plantar reflex is sometimes present in older children, but its absence is of little or no significance. Nor is neck rigidity by any means a constant finding. There are on the other hand, cases which show evidence of what I like to describe as objection rather than rigidity in response to flexion of the neck. This I realize is only a matter of degree, nevertheless, I have found that sensing neck objection of this sort has helped me to anticipate the development of other and more conclusive signs.

If the child with tuberculous meningitis is an infant the fontanelle provides valuable clinical evidence. Here again, however, it is, I am convinced, well worth while trying to recognize differing degrees of departure from normal in an attempt to arrive at an early diagnosis. There can of course be no mistaking the tense pulsating fontanelle, but before this stage is reached it is sometimes possible to appreciate a fullness characterized by "bogginess" rather than by tension. Where this occurs in the presence of other suggestive findings it is of undoubted value in arriving at a diagnosis. Even where there is neck rigidity, head retraction of any degree is unusual, and where it is present a noticeably thick exudate in the medullary region is usually found at necropsy.

In general, then, it can be said that true neck rigidity, head retraction, and Kernig's sign, as they are found in other forms of meningitis in childhood, are by no means typical where infection is due to the tubercle bacillus. A more common finding at this stage is the sudden appearance of motor palsy albeit slight, in some form or another. Ptosis, unilateral or bilateral, and strabismus, usually internal, are the most common. Either of these may be associated with irregularity or inequality of the pupils. More rarely, but not altogether uncommonly, a limb or the facial muscles are involved, sometimes temporarily for some days, only to reappear.

So much for the stage of irritation, which usually lasts for a week but which more often than is sometimes stated may last longer than that.

#### Third Stage

I do not propose to enlarge upon the terminal stage. Suffice it to say that during this stage the slow pulse gives place to a rapid pulse, coma develops from drowsiness, and the temperature from being moderately irregular rises progressively. There may be delirium, convulsions are common—so also is incontinence of urine and faeces, flushing is pronounced, and wasting is increasingly rapid. The gaunt facies, the dry lips, the haggard expression, and the rattle of the throat make for one of the most trying ordeals parents at the bedside of a dying child have to face. I have dwelt on this because I feel that in striving to improve our knowledge of the condition we

should be mindful of the anguish that we may be able to save parents to whom at present we can offer little comfort, only understanding

Such, then, is the unfolding clinical picture presented by tuberculous meningitis in childhood. This picture contains three salutary warnings, one related to each phase of the picture. Briefly these lessons are (1) The clinical picture in the third and terminal stage is so predominantly one of intracranial disease that sight is apt to be lost of the fact that infection of the meninges has been secondary to an earlier infection elsewhere in the body, (2) The clinical picture in the second stage is sufficiently typical to suggest a correct diagnosis, but it is not dependent for its characteristics on findings associated with other forms of meningitis in childhood, (3) The symptoms which go to make the clinical picture of the first or prodromal stage have four more or less constant characteristics—namely, vagueness, insidiousness, a slow progressiveness, and a certain ominous persistence when reviewed over a period of time.

### The Problem of Early Diagnosis

It is to this baffling prodromal period that I shall devote the rest of this address. When we are faced with the problem of diagnosis in a child presenting vague but rather persistent symptoms, what factors should or should not raise the question of tuberculous meningitis?

And here I would say at the outset that I think we would succeed in diagnosing tuberculous meningitis earlier were we, in the first place at least, to consider whether active tuberculous infection is present rather than whether there is or is not meningitis. In saying this I am influenced by two things. First, it is recognized that there is a special risk of meningitis occurring during the three months which succeed primary infection, and, secondly, the symptoms of primary infection, of early miliary infection, and of early meningeal involvement are vague and indefinite. The symptoms, consisting of nothing more than slight fever in a child who for some unexplained reason has gone off his food or off his feet, may pass unrecognized.

I have already referred to the importance of headache, constipation, and vomiting in the early symptomatology. Judged by the literature on the subject there is no agreement on which of these three is the earliest. As I have said, in my experience vomiting has almost always been the first. A point of some importance, more especially in the case of older children, is that mention of vomiting is often omitted in the mother's description and that reliable information is got only if leading questions are asked. The reason for this is that the vomiting bears no relation to food, has no periodicity, and occurs at long intervals. A point concerning the constipation is that more often than not it is associated with a clean tongue. In most cases the headache is frontal, but in the early stages at least it is not usually severe enough to keep the child awake.

Quite apart from actual wakefulness at night, restlessness may be an early complaint. Sometimes by restlessness at night a mother means irregular and unusual breathing during sleep, and observations which I made on cases of early tuberculous meningitis when holding resident hospital appointments certainly did suggest that irregular breathing in sleep is by no means uncommon at an early stage in these cases. Other forms of restlessness in sleep have been given a good deal of prominence in the literature but I have not found them to be constant findings. More commonly a mother comments, without any suggestion of worry, that *her child is more difficult to waken in the morning*. This may mean little, but if later the mother remarks that her child is not only difficult to waken in the morning but has gone to sleep after tea or has volun-

tarily expressed a wish to go to bed earlier than usual, the clinician must be very much on the alert.

While on the question of information given by a mother there is another aspect which I should like to stress. Important as questions and replies may be, very often it is the aside made by the mother or her casual observation that sounds a note of warning. The mother is the first to note changes in temperament in her child. Because she is perplexed she is not always good at describing what she has noticed. If a mother talks about her girl or boy "being different" or "not himself" it is always worth while probing deeper. Disinclination to play is an early sign of many illnesses in childhood. But on many occasions it has struck me that this temperamental change or adjustment goes a stage further in cases of tuberculous infection. The child not only limits his physical and mental activities but, over and above that, withdraws from contact with others and retires within himself. He wishes neither to be spoken to nor to talk. He shows a preference for a chair in the corner. He is moody to the point of sullenness, and then, for no apparent reason and with altogether surprising suddenness, recovers some but not all of his former vivacity and interests. A certain sense of tiredness, perhaps even weariness, persists and increases as the moods come and go, but still the eyes remain bright and the pupils a little dilated. I do not wish to suggest that the picture I have drawn is diagnostic, but I do say that in the presence of other indefinite symptoms this fitful temperamentalism in association with tiredness is an important feature of most cases.

### Physical Signs

And what of physical appearance and physical findings as distinct from emotional behaviour? There is no typical appearance. While it is true that many children show evidence of previous disease or of debility of varying degrees, many others are apparently robust, well clad, and rosy-cheeked. In the individual case an appearance of ill health is of value in diagnosis, but the fact that a child looks physically healthy and does not seem to have lost weight in no way offsets the possible significance of other symptoms suggestive of tuberculous infection. On the other hand, no matter what my own assessment of a case may be, I never ignore a mother's suspicion, much less her statement, that a child has got thinner. And when I have compared my own observations with those of parents I have usually found that any discrepancies have been due to the latter sensing an early almost infinitesimal loss of subcutaneous tissue as yet unaccompanied by wasting of muscles.

Another feature worth noting is the tendency of many of these patients—including those of apparently robust physique—to show an unnatural and early dryness of the skin. This is usually most in evidence over the trunk, but sometimes it first appears over the inner aspects of the thigh. Although of itself a small point, I mention this minor observation as being one of many which go to make up the elusive clinical picture of some cases of early tuberculous meningitis.

There are of course other aspects of a case which may legitimately influence diagnosis. Chief among these is a history of exposure to infection or the presence of tuberculosis elsewhere in the body. So far as exposure is concerned there is, I think, a tendency to jump to conclusion too readily. It is not the fact that a member of the household has had open tuberculosis that matters, but the fact that the patient has or has not been in contact with the suspected person at a material time (Table I). My experience on this particular point is mainly based upon hospital work in Edinburgh and to a smaller extent in the south, but it has always surprised me how very ofte

TABLE I—*Environmental Factors\**

1 History of contact in connexion with cases due to human infection or to infection of unknown type	
No. of cases lacking reliable history of contact	48
No. of cases with no reliable history of contact but with history of tuberculosis in family	42
No. of cases established as having been exposed at a material time to contact with	
A Unsuspected open infection in	
a A parent	20
b A sibling	5
c A grandparent	4
d Other relative	9
e A member of the household (or children's community) not a relative	13
f Neighbours	6

Never boiled	13	5
Occasionally boiled	3	4
Pasteurized T T or "invariably boiled"	2	4

\* The cases included in the series were drawn from many administrative areas in both Scotland and England

careful inquiry can establish that there has been an unquestionable risk of exposure. Another finding which has impressed me is the frequency with which there is a history of previous children in the family having died from tuberculosis. In the series on which I am basing my remarks this was true of no fewer than 17 children, representing over 8% of all the cases. Equally striking in this same series is the fact that no fewer than 25 (12%) of the 205 cases occurred in first children who at the time of their death were "only" children. Why this should be I am uncertain. Nor can I explain why it is that so often this dread form of disease seems to pick out "the bonniest of bairns."

### Tuberculin Skin Test

Where tuberculous infection is known to exist elsewhere in the body the occurrence of new symptoms, no matter how vague or slight, should at least bring to mind the possibility of meningeal involvement. Even in those cases in which infection may have been previously suspected and not established, recourse should in such circumstances be had to radiological examination without delay. The fact remains, however, that in a large proportion of children known to be suffering from intracranial tuberculosis it is not possible to establish during life the presence of infection elsewhere in the body. I would suggest that this common experience has its lesson. We should accept that we cannot expect physical signs to help us very much where early meningitis is suspected. That being so, much greater use should be made of tuberculin skin tests to determine at an early stage whether or not a child has in fact been infected and acquired sensitivity. It may be argued that these tests are apt to fail in cases of tuberculous meningitis. That is true, but in my experience only rarely, and I am yet to be convinced that it ever fails in the early stages of the condition. In part the explanation lies in the fact that severe anaemia, impaired peripheral circulation, hyperpyrexia, and cachexia, which may contribute to failure or suppression of skin reactions, are not present in the early stages of tuberculous meningitis. Subject to the employment of a reliable method I have always looked to tuberculin skin-testing for invaluable help. While the Mantoux test is the most reliable method, I prefer the multiple puncture test for use in the home as being simpler and almost as reliable as the Mantoux and because it is unquestionably more reliable than the jelly or patch test. To get a negative reaction to a reliable test in a vague

worrying case can, by allowing a more favourable prognosis at an earlier stage, save parents as well as physician much anxiety. A positive reaction in the presence of signs or symptoms even vaguely suggestive of meningeal involvement, more especially in a child of 6 years or under, should point to the necessity for immediate admission to hospital for further investigations.

### Lumbar Puncture

If the tuberculin skin test is of value, what of lumbar puncture? In what I have said I have tried to keep the problems of the family doctor to the forefront, and the question of whether to perform a lumbar puncture or not often constitutes a problem in itself. It is always wise to study the parents before deciding to do a lumbar puncture in the home. There is the risk that in their distraction the relatives may attribute any subsequent developments to the puncture. And it is, I think, well to remember that in the early stage of tuberculous meningitis the findings in the fluid, while they may be valuable, are not likely to be conclusive. The fluid is always clear but not usually under pressure in the early stage. In the later stages a typical fluid shows a cellular increase mainly mononuclear in character, an increase in protein, a decrease in sugar, and a pronounced decrease in chlorides. It has been said that a chloride content of less than 650 mg per 100 ml is virtually diagnostic. This simplifies the position overmuch. A chloride content of 650 mg is suggestive of tuberculous meningitis, but can in my experience occur where intracranial inflammation is attributable to organisms other than the tubercle bacillus.

In the early stages of tuberculous meningitis the cerebrospinal fluid findings vary considerably. There may or may not be an increase in the cell content. It is no uncommon finding for polymorphs to be as numerous as lymphocytes. In some cases the polymorphs are actually in excess. This is more likely to occur where the patient is a small child and where the condition is running a more than usually rapid course. Great differences are found in the protein content. A normal figure or one as high as 400 or 500 mg per 100 ml may be obtained.

A reduction in chlorides is the exception and not the rule in the early stages of tuberculous meningitis. In nine cases, each of which I had under continuous clinical observation for over five weeks and from each of which cerebrospinal fluid was obtained at intervals of not less than five days, early signs of irritation preceded any significant reduction of chloride content of the fluid. On the other hand, a low sugar content appeared some four weeks before death in four of these cases. Whereas the sugar content tended to fluctuate, the protein content, which rose comparatively early, continued to increase gradually and progressively to a level which varied for each case but which, once attained, was maintained until death.

It will be appreciated, therefore, that in the early days of tuberculous meningitis there is a certain element of chance in what one may find in the fluid. And where lumbar puncture is performed in the early stage the findings are likely to provide no more than equivocal information to be evaluated in relation to clinical observations.

There is just one reservation I must make in this connexion. If cerebrospinal fluid from a well-established case of tuberculous meningitis is allowed to stand, a "shimmery" frail coagulum appears in the course of a few hours. Sometimes this occurs in fluid obtained early in the course of the disease. On four occasions I have known this coagulum to appear during the prodromal stage. Allowing that the likelihood of this occurring so early is slight, it is, I think, worth looking for in any suspected case, because if found

it is so highly suggestive. The same may be said of choroidal tubercles and changes in the optic disks. These were encountered at an early stage in only five of my series, but were of value in allowing of more rapid diagnosis than would otherwise have been possible. Extensive miliary spread was demonstrated post mortem in all five cases.

### The Factor of Age

And now I come to my last point, which I have left to the end because it has a bearing on almost all that I have already said. As is well known, the form which a particular disease assumes may differ in infancy as compared with older childhood. This tendency applies to tuberculous meningitis and in particular to the prodromal stage of the condition. A point of importance in diagnosis is that tuberculous meningitis is rare under 6 months of age. It occurs with greatest frequency in the second and third years of life (Table II). This is of some importance

TABLE II—Age Distribution

Age Period	No of Cases	Age Period	No of Cases
6 months and less	6	7-8 years	6
6 months-1 year	31	8-9 "	8
1-2 years	45	9-10 "	3
2-3 "	37	10-11 "	5
3-4 "	18	11-12 "	4
4-5 "	16	12-13 "	1
5-6 "	11	13-14 "	2
6-7 "	10	14-15 "	2

because the condition tends to run a more rapid course in infancy than in older childhood. Of the triad—headache, vomiting, constipation—headache is rarely a recognizable feature in infants. It is sometimes said that headache is indicated by screaming and by the hands being raised to the head. This is contrary to my experience. My impression is that the infant with early tuberculous meningitis tends to be quiet rather than noisy. Often, indeed, it is unnatural drowsiness that first gives a hint of the presence of trouble. Most commonly, however, vomiting is the first symptom. Sometimes, and I think frequently, it is preceded by a sudden and complete loss of appetite. Almost invariably it is followed by constipation.

In contrast with the condition in older children the vomiting tends to be persistent rather than erratic, but if a careful history is taken it will usually be found that anorexia has preceded even the first vomit. As I said earlier, the fontanelle often raises suspicion at an early stage. So also does a certain strangeness in the expression—a strangeness usually described by the mother as vacant, but which to me sometimes suggests a sense of apprehension. Eventually the expression becomes fixed. Nor is there, I think, any question that convulsions are more likely to occur early in infants, whereas in older children they are usually a late rather than an early sign. It is rare to come across recognizable papilloedema in the small baby.

Another point worth mentioning is the frequency with which there is a history of recent ear discharge in cases of tuberculous meningitis in infants. My experience is that it occurs in some 20 to 30% of those under 3 years of age. There is always the risk that it may delay the real diagnosis. For what it is worth I might mention my impression that it is usually, if not only, in those cases of tuberculous meningitis with associated otitis that the child is seen holding his head or ears as if in pain.

### Onset of Symptoms in Bizarre Form

So much, then, for the differences in infancy as compared with other ages. I need hardly say that we must

always be prepared for the case which presents at onset in an altogether unusual, even bizarre, form. I have twice had children brought to me on account of ptosis which had developed suddenly and which later proved to be the beginning of meningitis. In five other cases the first complaint was of paresis of a limb or part of a limb, or of the facial muscles. In two of these five cases the paresis disappeared only to be followed after an interval by the symptoms of early meningitis. In two cases difficulty in walking was the first thing noticed. In another child brought on account of hysteria, a coarse intention tremor of one hand was observed in the out-patient department. Ten days later the child showed signs of early meningeal involvement. Where there is inflammatory involvement of the cervical cord the head may be held in any grotesque position, and I have twice had infants referred to me in which torticollis was the first outward evidence of tuberculous meningitis.

Bizarre symptoms lacking other explanation—and the include the precipitately occurring convulsion lacking apparent organic or reflex association and the sudden development of gross athetoid-like movements in older children—should always raise the question of tuberculous meningitis. So, I think, should a history of headache dating back to an accident some time previously. This may seem rather irrational, but there was a history of accident in no fewer than 7% of my cases. Even allowing that the connexion between accident and illness was more a figment of the mother's distraught imagination than a reality in some instances, the figure is too high to be ignored, and it has some pathological justification if Rich's theory concerning meningeal infection is accepted.

Lastly, importance should always be attached to child's past health history. Analysing my records, my impression is that the point of significance is not so much whether the child has had measles or whooping-cough recently as whether he has or has not had a number of debilitating conditions, more especially if they have followed in rapid succession or have been of pronounced severity.

Robert Whytt concludes his classic with a note on "The Cure of a Dropsy in the Brain." In this note he says "In this disease could be known early, and before any considerable quantity of water has been collected, it might probably sometimes be cured." He goes on to say "As it never discovers itself till so much water is accumulated, as to disturb the action of the brain we have little to hope from any medicine."

Whytt thought in terms of "purgatives, diuretics, blister frictions, exercise, and diet." To-day we are at the start of giving trial to streptomycin, which may provide us with some of the answers we seek. As yet we cannot say, but success in the use of streptomycin, whether for research purposes or as a form of therapy, will, I quote Whytt again, depend on "knowing the disease early."

The United Kingdom Trade Commissioner at Delhi has forwarded to the Board of Trade the following report of an answer to a question in the Constituent Assembly of India (Legislative): "The country is self-sufficient in regard to the common vaccines used for public health purposes, such as cholera vaccine, T.A.B. vaccine, plague vaccine, and vaccine lymph. The indigenous production of other drugs is inadequate to meet the country's requirements, and the hospitals obtain Indian-made medicines to the extent they are available. The question of increasing the production of certain essential drugs is under the consideration of the Government of India in the Ministry of Industry and Supply in consultation with the Ministry of Health. In view of the shortage of foreign currency the Government are already following a restrictive policy in respect of import of medicines and drugs, including patent medicines. Drugs are allowed to be imported only if they are essential."

## "MUSHROOM" POISONING DUE TO AMANITA PHALLOIDES

BY

DAVID LEWES, M.A., B.M., M.R.C.P.

Late Squadron Leader, Medical Specialist, R A F V R

Edible fungi have been a favourite culinary delicacy for centuries. Mushrooms were recognized as a valuable form of food by the ancient Babylonians and early Romans, who employed them in large quantities not only as a delicacy for the tables of the rich but also as a staple article of diet of the poorer classes.

Although the ancients were possessed of considerable knowledge regarding edible fungi and poisonous varieties were well recognized, many fatalities must have occurred. Records of death from fungus poisoning, often amongst eminent people, figure prominently in contemporary writings, especially those of Pliny, but the earliest record of fatal poisoning dates back over two thousand years. In the fifth century B.C., when Euripides the poet was at Icarus, a woman with her two grown-up sons and a married daughter "were destroyed by pitiless fate in one day" after eating fungi gathered from the fields. In this instance it is probable that *Amanita phalloides* (Death Cap) was the cause of the tragedy, for besides being the most poisonous fungus known it is responsible for more than 90% of all deaths due to mushroom poisoning and is attended by a mortality rate of from 50 to 70% (Ford, 1923). Ramsbottom (1945) states that a death rate as high as 90% has been claimed. Although this percentage is unduly high as an overall figure, there are many examples of a 100% fatality rate in particular groups in which all members partaking of a meal have succumbed (Ford, 1923).

Mushroom poisoning is a commonplace on the European continent, while 200 fatal cases are said to occur annually in Germany alone. In this country but few cases have been reported in the literature. Thus Dubash and Teare (1946), recording four fatal cases, could trace only 21 reported cases of mushroom poisoning with 14 deaths in Great Britain between 1930 and 1942. Birch (1946), quoting from the Registrar-General's record, could find only 38 cases of fatal fungus poisoning in England and Wales between 1920 and 1945.

As the time of year is now upon us when *A. phalloides* will again be abundant in the woods and adjoining pastures, and when many continentals are still in our midst, two further cases of Death Cap poisoning seem worthy of report.

### The Present Cases

Two German prisoners of war—H W, aged 29, and J W, aged 30—were admitted to an R A F hospital on the morning of Sept 13, 1946, complaining of intermittent seizures of cramp-like abdominal pain accompanied by severe attacks of vomiting and violent purgings. They gave the following story. On the morning of Sept 11 they had gathered "mushrooms" from a near-by wood, and the next day, after preparation, the fungi were boiled in water for three-quarters of an hour before being fried. The failure of the cooking "mushrooms" to blacken a silver coin was considered proof that the meal would be safe, and each man ate approximately half a pound of mixed fungi. They found the meal most palatable and did not complain of ill effects until nine and twelve hours later respectively. In both cases initial symptoms consisted of severe vomiting, soon to be followed by intermittent attacks of griping upper abdominal pain and diarrhoea. Symptoms continued throughout the night, and on admission to hospital on Sept 13, eighteen hours after ingestion, diarrhoea and vomiting had taken place fifteen times in H W and ten times in J W.

The patients were first seen personally on Sept 14 the day after admission. Diarrhoea with vomiting had occurred almost

two-hourly in J W. Fluids by mouth and an intestinal sedative had been prescribed. On questioning the patients the history of ingestion of "mushrooms" followed by a silent period of many hours before the onset of symptoms made a diagnosis of poisoning by *A. phalloides* virtually certain. Treatment was therefore conducted along these lines without waiting for more definite proof. Additional evidence, however, was soon furnished by the patients themselves. One volunteered that the types of fungus they had gathered were chiefly those with large bulbous stems surrounded in their lower parts by a membrane or volva (see Fig)—characteristics typical of the *Amanita* group. They

Photograph of specimens of *A. phalloides* at different stages of growth. Note the well marked volva at the base of the stem, the faint dark (green) striations on the surface of the cap, and the dead-white gill-plates seen in the oldest specimen.

also identified a specimen picked by a fellow prisoner of war (who had also partaken of a small quantity of the mushrooms but had been unaffected) as similar to some of the fungi they had eaten. This specimen proved to be *A. phalloides*. Later a personal visit to the wood accompanied by a colleague with sound botanical knowledge showed that in an unselected picking from the area concerned *A. phalloides* constituted about 10% of the fungi collected. *A. rubescens* (Warty Caps), a non-poisonous variety, were plentiful, but no common mushrooms were identified. It was roughly estimated that in half a pound of uncooked fungi each man had probably eaten one or at most two specimens of *A. phalloides*.

### Clinical Examination

Seen on Sept 14 the second day, both patients, of good physique and development, were exhausted and somewhat dehydrated, especially H W, in whom symptoms had begun earlier and were more severe. Thirst was marked. Mental aberrations or nervous involvement—a muscarine-like effect that is sometimes observed—were not a feature in either case, except that H W was a little disorientated and excitable, although able to co-operate and give a rational history. There was no sign of jaundice or haemorrhagic tendency in either case, while lacrimation, sweating, and salivation were absent. The tongue was dry and coated and the breath heavy. The skin and especially the extremities felt cold, but were without lividity or cyanosis, the temperature was subnormal and the pulse small and rapid. On abdominal examination H W complained of tenderness under the right costal margin, in neither case was the liver or spleen palpable. No abnormal physical signs were found in the nervous system, and the rest of the examination was essentially negative. The urine, normal to routine tests, was small in amount and concentrated. Vomitus and excreta contained little solid matter, considerable mucus, but no macroscopic blood in the early stages.

### Treatment and Management

All efforts to obtain supplies of antiphallenic serum proved unsuccessful. Gastric and high colonic lavage with 1% saline solution was performed three times on the day after admission.

and daily for the next three days. On each occasion lavage was continued until the return was clear. This involved as much as three gallons of fluid during the early part of treatment. Two ounces (57 cc) of 50% magnesium sulphate were left in the stomach. The effect of lavage produced an immediate and striking diminution of vomiting and diarrhoea, which ceased in the case of J W after the first treatment.

On Sept 14, 5% glucose in normal saline, four to five litres in 24 hours, intravenously, was begun, this was continued for four days, together with 15 units of soluble insulin and 10 mg of vitamin K four-hourly in an attempt to prevent or minimize liver damage, which was fully anticipated. Apart from ice to suck, all fluid requirements were met by parenteral administration. Atropine 1/100 gr (0.65 mg) and morphine 1/4 gr (16 mg) were prescribed to control restlessness and pain during the first three days.

On the sixth day unlimited glucose drinks and small quantities of citrated milk were substituted for the intravenous drip, but four-hourly insulin injections, combined with vitamin K and vitamin B<sub>1</sub> 12,000 units and 10 ml of 10% solution of calcium gluconate parenterally, were continued for a further forty-eight hours. A light diet rich in protein and carbohydrate was then prescribed and steadily increased until discharge from hospital on Oct 21, when the patients were taking a normal diet.

#### Clinical Course of Case 1 (H W)

Although gastric and colonic lavage decreased the frequency and severity of vomiting and diarrhoea, both persisted until the evening of the third day, when these symptoms gave way to complaints of upper abdominal pain. At this time the patient was unduly drowsy and lethargic. Examination revealed tenderness under the right costal margin, but the liver was not found to be enlarged. On the fourth day definite jaundice of the sclerotics was noted, but the skin was normal in colour. The urine, small in amount, was dark amber and concentrated. The patient, however, felt much better, drowsiness was less marked and he was more alert, nor was there any complaint of abdominal pain or sign of liver enlargement. Clinical improvement from this point was rapid despite an intermittent pyrexia, which reached 102° F (38.9° C) on Sept 17 and persisted with gradual defervescence until Sept 27. All signs of jaundice had cleared by Sept 21, and urinary output, which had previously been unsatisfactory, rapidly improved.

**Laboratory Investigations—Sept 14**—Urine N A D. **Sept 17**—Blood Hb, 94% (Sahli), R B C, 4,280,000, W B C, 5,400 per c mm (polymorphs 77% lymphocytes 20% monocytes 3%). Urine Urobilinogen +, albumin and sugar nil, no deposit. **Sept 18**—Total plasma proteins 5.5 g per 100 ml, albumin-globulin ratio, 1.6:1. **Oct 2**—Electrocardiogram Physiological, no evidence of bundle-branch block (a feature reported by Hyman 1928). **Oct 4**—B S R 35 mm in first hour (Westergren). **Oct 5**—Total plasma proteins 6.5 g per 100 ml, albumin-globulin ratio, 5:1. **Oct 7**—Serum bilirubin Less than 0.5 mg per 100 ml. **Oct 17**—B S R 14 mm in first hour (Westergren).

#### Clinical Course of Case 2 (J W)

On the second day after the first gastric and colonic lavage, for which three gallons (13.64 litres) were required, the patient felt more comfortable, while vomiting and diarrhoea ceased completely from this time. The patient still complained of pain under the right costal margin, but there was no jaundice or evidence of hepatic enlargement.

The condition appeared to have improved on the third day despite pyrexia to 101.6° F (38.7° C). Apart from superficial ulcers of lips and tongue there were no complaints, and the patient felt much better. Clinical examination was negative. Anuria, however, persisted throughout the day, and in the evening his condition rapidly deteriorated. He complained of generalized aching pain of sudden onset and severe right sided upper abdominal pain, requiring morphine for relief. A bowel action, consisting of a very pale stool, was accompanied by passage of a few ounces of dark amber urine.

On the fourth day, after a noisy restless night when morphine and atropine had to be administered, the patient became more restless and very drowsy, although rousable. His chief complaint was severe abdominal pain. Jaundice of sclerotics and skin, although not deep, was obvious, and pruritus was troublesome. No haemorrhage or petechiae were seen. Abdominal examination revealed extreme tenderness in the epigastrium and under the right costal margin. The liver was enlarged one to two fingerbreadths, the spleen was not palpable. Temperature was 100° F (37.8° C), pulse, 64 a minute, and regular.

Restlessness, with sleep for brief periods, occurred throughout the next night, but by the fifth day his condition showed some improvement. Jaundice and hepatic enlargement were unchanged, but abdominal pain and tenderness were less. Examination of the lungs showed coarse basal crepitations which persisted for several days, there were no respiratory symptoms. Following this acute attack the patient's condition steadily improved, but more slowly than in Case 1. Jaundice, never deep, persisted together with hepatic enlargement until Sept 28 (16th day), when he was free from all symptoms and taking a light diet.

**Laboratory Investigations—Sept 17** Urine SG 1020, urobilinogen +, albumin +, sugar, nil deposit—leucocytes with granular debris. Plasma proteins Total 5.2 g per 100 ml, albumin-globulin ratio, 1.8:1. Blood Hb, 101% (Sahli), R B C, 4,820,000, W B C, 5,000 per c mm (polymorphs 71%, lymphocytes 19%, monocytes 10%). **Sept 18**—Serum bilirubin 1.25 mg per 100 ml. **Oct 2**—Electrocardiogram Physiological. **Oct 8**—Plasma proteins Total, 6.6 g per 100 ml, albumin-globulin ratio, 4:1. Serum bilirubin 0.5 mg per 100 ml.

Both patients were confined to bed for three weeks from the time of admission to hospital, they returned to duty on Oct 21.

#### Discussion

*Amanita phalloides* produces two main active principles—phallin and amanita toxin. The former, first described by Kobert (1891), is an alcohol-insoluble haemolysin. It is relatively unimportant in cases of poisoning, for, being an easily decomposed glucoside, it is rapidly destroyed by heat and by digestive juices. Amanita toxin, the essential poison, is an alcohol-soluble indole or aromatic phenol derivative. It is resistant to heat, to drying, and to digestive juices, and in experimental animals it produces most of the lesions which are described in fatal cases of *A. phalloides* poisoning in man (Ford, 1908, 1923).

The susceptibility of different individuals to the amanita toxin varies, but surprisingly small amounts of the fungus and even a portion of a single specimen may prove fatal, especially when eaten raw (Plowright, 1879). The case histories and course of the illness reported above indicate that

Table showing the comparative relationship of early and delayed symptoms and signs

Case	Period of Gastro intestinal Symptoms			Period of Delayed Hepato renal Damage						
	Silent Period (Hours)	Severity of D and V	Total Length of Symptoms (Hours)	Abdominal Pain and Tenderness	Duration of Jaundice (Days)	Pruritus	Liver Enlargement	Urine	Serum Bilirubin	Total Plasma Proteins Alb/Glob Ratio
1	9	+++ attacks before admission	69	+	Slight (6 days)	Nil	Nil	Urobilin + albumin nil no deposit	—	Sept 18 5.5 g ratio 1.6:1 Oct 5 6.2 g ratio 5:1
2	12	++ attacks before admission	38	+++	++ (13 days)	+	1-2 finger breadths	Urobilin + albumin + polys and deposit +	1.25 mg/100 ml	Sept 17 5.2 g ratio 1.8:1 Oct 8 6.6 g ratio 4:1

only a small quantity of *A. phalloides* had been eaten by the patients—a contingency made all the more probable by the fact that a third individual partaking of the meal was unaffected. Thermostability of amanita toxin was well demonstrated by its resistance to boiling and frying for almost an hour (at a maximum temperature of about 140° C), the silver-spoon test recommended by Atkinson (1900) proved a misleading and dangerous criterion by which to judge whether the "mushrooms" were safe or not, and, finally, *A. phalloides* was palatable and even pleasant to eat.

The long delay interval of nine and twelve hours respectively before the onset of symptoms emphasizes the important point made by Birch (1946), that in any case of mushroom poisoning an interval of eight hours or more between ingestion and symptoms should be regarded as diagnostic of *A. phalloides* poisoning. The severity of the gastrointestinal symptoms in the early stages of the illness contrasted with the surprisingly mild hepato-renal damage which took place later (see Table). The importance of eliminating factors in assisting recovery is indicated by the fact that the patient with the shorter silent interval and the more severe and prolonged diarrhoea and vomiting sustained less liver damage than his colleague, whose condition in the early stages was considered the more satisfactory. In addition, poisoning by *A. phalloides* combined with other species of fungus has a better prognosis than poisoning by *A. phalloides* alone, the reason for this being that other types of fungus often cause earlier diarrhoea (Vander Veer and Farley, 1935).

### Summary and Conclusions

Mushroom poisoning due to *Amanita phalloides* in two German prisoners of war is described. Both patients recovered.

The severity of the gastro-intestinal symptoms in the early stages of the illness contrasted with the mildness of the delayed hepato renal damage.

The delayed effects of poisoning were more severe in the patient with the longer silent period before the onset of symptoms and with the less pronounced and protracted diarrhoea and vomiting.

The ability of the gastro intestinal tract to eliminate the toxin of *A. phalloides* and the thoroughness with which this elimination is assisted by early and efficient gastric and colonic lavage, are regarded as factors of the greatest importance in determining recovery.

My thanks are due to the Director General of Medical Services for permission to publish this paper and to Professor John McMichael for his helpful criticism and advice. The invaluable assistance of Squadron-Leader Meredith Brown, who identified specimens of fungi, and the keen co operation of Flight-Lieut E R Arnold, who was responsible for the care of the patients and for carrying out treatment, are much appreciated.

The Ministry of Health has issued two leaflets explaining how to get dental treatment or sight tests and spectacles under the National Health Service. Members of the public can get copies of them from the offices of the executive councils (address from any post office) at local offices of the Ministry of National Insurance, and at various other centres, such as citizens' advice bureaux.

## TREATMENT OF GENU VALGUM

### THE DISCARDED IRON

BY

H A BRITAIN, MCh, FRCS

Senior Orthopaedic Surgeon Norfolk and Norwich Hospital

The psychological effect, both on child and on parent, of wearing irons is usually unpleasant. There are occasionally exceptional people, like the late President of the United States, who achieve superiority in spite of their disability. That is possibly because the essential necessity for wearing irons has been revealed to them and they have been told that irons are necessary for progression or even existence.

Every orthopaedic surgeon who has served during the war must have experienced a thrill on his return to civilian practice on seeing as a young adult apparently cured a child who had been under his treatment five years previously. He may be labouring in the fields, she may be soignée with lipstick and rouge. Yet if treatment has extended over several years it is always easy to detect in these patients a difference from others. An intangible shyness or barrier is present. It might be called an inferiority complex, but it is a sequel of prolonged immobilization, with which social segregation is invariably associated. This result may be regrettable, but it is tempered by the fact that such treatment has been inescapable.

In quite a different category is the child who has to wear an instrument which proclaims to all that he or she is a "cripple," though in truth such an instrument is merely corrective and not essential. Here, leading all the rest, is the knock-knee iron or brace, an appliance of very doubtful value.

This paper is based on impressions derived from the treatment of 8,000 cases of genu valgum treated over a period of 15 years, and has been prompted by seeing children returned to East Anglia after evacuation to other parts of England where treatment was carried out with knock-knee braces and without appreciable results.

### Aetiology

Jones and Lovett (1929) describe knock-knee under the heading of rickets. They, however, stress that rickets is not the only cause of knock-knee, and mention tuberculosis of the knee-joint and infantile paralysis as well as fractures in the neighbourhood of the knee-joint with malposition and epiphyseal injury. "Loose knees" in children are also mentioned, and I wish to emphasize these as being the chief cause. McMurray (1943) says "This very common deformity begins as a rule in early childhood, following on rickets," and ten lines later on he states "As a rule, deformity is due to this overgrowth of the inner side of the femur, the alignment and shape of the tibia remaining normal." Mercer (1943) states "The deformity of knock-knee develops, as a rule, in early childhood, and is almost invariably due to rickets."

Few orthopaedic surgeons now believe that rickets is the commonest cause of knock-knee, yet this claim holds pride of place in the three textbooks mentioned. I think that knock-knee is due to (1) laxity of ligaments or loose knees, as mentioned by Jones and Lovett (1929), (2) quadriceps insufficiency, and (3) the child being overweight.

It may be argued that if the knee is loose why does genu valgum not occur at the knee instead of genu valgum? The femora are much wider apart at the level of the great trochanters, and slope inwards towards the knee, so that the tendency is normally to valgus. Furthermore, the external lateral ligament of the knee is a thick and very strong structure, reinforced by the ilio-tibial band, and

and daily for the next three days. On each occasion lavage was continued until the return was clear. This involved as much as three gallons of fluid during the early part of treatment. Two ounces (57 cc) of 50% magnesium sulphate were left in the stomach. The effect of lavage produced an immediate and striking diminution of vomiting and diarrhoea, which ceased in the case of J W after the first treatment.

On Sept 14, 5% glucose in normal saline, four to five litres in 24 hours, intravenously, was begun, this was continued for four days, together with 15 units of soluble insulin and 10 mg of vitamin K four-hourly in an attempt to prevent or minimize liver damage, which was fully anticipated. Apart from ice to suck, all fluid requirements were met by parenteral administration. Atropine 1/100 gr (0.65 mg) and morphine 1/4 gr (16 mg) were prescribed to control restlessness and pain during the first three days.

On the sixth day unlimited glucose drinks and small quantities of citrated milk were substituted for the intravenous drip, but four-hourly insulin injections, combined with vitamin K and vitamin B<sub>1</sub> 12,000 units and 10 ml of 10% solution of calcium gluconate parenterally, were continued for a further forty-eight hours. A light diet rich in protein and carbohydrate was then prescribed and steadily increased until discharge from hospital on Oct 21, when the patients were taking a normal diet.

#### Clinical Course of Case 1 (H W)

Although gastric and colonic lavage decreased the frequency and severity of vomiting and diarrhoea, both persisted until the evening of the third day, when these symptoms gave way to complaints of upper abdominal pain. At this time the patient was unduly drowsy and lethargic. Examination revealed tenderness under the right costal margin, but the liver was not found to be enlarged. On the fourth day definite jaundice of the sclerotics was noted, but the skin was normal in colour. The urine, small in amount, was dark amber and concentrated. The patient, however, felt much better, drowsiness was less marked and he was more alert, nor was there any complaint of abdominal pain or sign of liver enlargement. Clinical improvement from this point was rapid despite an intermittent pyrexia, which reached 102° F (38.9° C) on Sept 17 and persisted with gradual defervescence until Sept 27. All signs of jaundice had cleared by Sept 21, and urinary output, which had previously been unsatisfactory, rapidly improved.

**Laboratory Investigations**—Sept 14—Urine NAD. Sept 17—Blood Hb, 94% (Sahli), RBC, 4,280,000, WBC, 5,400 per c mm (polymorphs 77% lymphocytes 20% monocytes 3%). Urine Urobilinogen +, albumin and sugar, nil no deposit. Sept 18—Total plasma proteins 5.5 g per 100 ml, albumin-globulin ratio, 1.6:1. Oct 2—Electrocardiogram Physiological. no evidence of bundle-branch block (a feature reported by Hyman 1928). Oct 4—BSR 35 mm in first hour (Westergren). Oct 5—Total plasma proteins 6.5 g per 100 ml, albumin-globulin ratio, 5:1. Oct 7—Serum bilirubin Less than 0.5 mg per 100 ml. Oct 17—BSR 14 mm in first hour (Westergren).

#### Clinical Course of Case 2 (J W)

On the second day after the first gastric and colonic lavage, for which three gallons (13.64 litres) were required, the patient felt more comfortable, while vomiting and diarrhoea ceased completely from this time. The patient still complained of pain under the right costal margin, but there was no jaundice or evidence of hepatic enlargement.

The condition appeared to have improved on the third day despite pyrexia to 101.6° F (38.7° C). Apart from superficial ulcers of lips and tongue there were no complaints, and the patient felt much better. Clinical examination was negative. Anuria, however, persisted throughout the day, and in the evening his condition rapidly deteriorated. He complained of generalized aching pain of sudden onset and severe right sided upper abdominal pain, requiring morphine for relief. A bowel action, consisting of a very pale stool, was accompanied by passage of a few ounces of dark amber urine.

On the fourth day, after a noisy restless night when morphine and atropine had to be administered, the patient became more restless and very drowsy, although rousable. His chief complaint was severe abdominal pain. Jaundice of sclerotics and skin although not deep, was obvious, and pruritus was troublesome. No haemorrhage or petechiae were seen. Abdominal examination revealed extreme tenderness in the epigastrium and under the right costal margin. The liver was enlarged one to two fingerbreadths, the spleen was not palpable. Temperature was 100° F (37.8° C), pulse, 64 a minute, and regular.

Restlessness, with sleep for brief periods, occurred throughout the next night, but by the fifth day his condition showed some improvement. Jaundice and hepatic enlargement were unchanged, but abdominal pain and tenderness were less. Examination of the lungs showed coarse basal crepitations which persisted for several days, there were no respiratory symptoms. Following this acute attack the patient's condition steadily improved, but more slowly than in Case 1. Jaundice, never deep, persisted together with hepatic enlargement until Sept 28 (16th day), when he was free from all symptoms and taking a light diet.

**Laboratory Investigations**—Sept 17 Urine SG 1020, urobilinogen +, albumin +, sugar, nil deposit—leucocytes with granular debris. Plasma proteins Total 5.2 g per 100 ml, albumin-globulin ratio, 1.8:1. Blood Hb, 101% (Sahli), RBC, 4,820,000, WBC, 5,000 per c mm (polymorphs 71%, lymphocytes 19%, monocytes 10%). Sept 18—Serum bilirubin 1.25 mg per 100 ml. Oct 2—Electrocardiogram Physiological. Oct 8—Plasma proteins Total, 6.6 g per 100 ml, albumin-globulin ratio, 4:1. Serum bilirubin 0.5 mg per 100 ml.

Both patients were confined to bed for three weeks from the time of admission to hospital, they returned to duty on Oct 21.

#### Discussion

*Amanita phalloides* produces two main active principles—phallin and amanita toxin. The former, first described by Kobert (1891), is an alcohol-insoluble haemolysin. It is relatively unimportant in cases of poisoning, for, being an easily decomposed glucoside, it is rapidly destroyed by heat and by digestive juices. Amanita toxin, the essential poison, is an alcohol-soluble indole or aromatic phenol derivative. It is resistant to heat, to drying, and to digestive juices, and in experimental animals it produces most of the lesions which are described in fatal cases of *A. phalloides* poisoning in man (Ford, 1908, 1923).

The susceptibility of different individuals to the amanita toxin varies, but surprisingly small amounts of the fungus and even a portion of a single specimen may prove fatal especially when eaten raw (Plowright, 1879). The case histories and course of the illness reported above indicate that

Table showing the comparative relationship of early and delayed symptoms and signs

Case	Period of Gastro intestinal Symptoms			Period of Delayed Hepato renal Damage						
	Silent Period (Hours)	Severity of D and V	Total Length of Symptoms (Hours)	Abdominal Pain and Tenderness	Duration of Jaundice (Days)	Pruritus	Liver Enlargement	Urine	Serum Bilirubin	Total Plasma Proteins Alb/Glob Ratio
1	9	+++ 15 attacks before admission	69	+	Slight (6 days)	Nil	Nil	Urobilin + albumin nil no deposit	—	Sept 18 5.5 g, ratio 1.6:1 Oct 5 6.2 g, ratio 5:1
2	12	++ 10 attacks before admission	38	+++	+(13 days)	+	1-2 finger breadths	Urobilin + albumin + polys and deposit +	1.25 mg/100 ml	Sept 17 5.2 g, ratio 1.8:1 Oct 8 6.6 g, ratio 4:1

only a small quantity of *A. phalloides* had been eaten by the patients—a contingency made all the more probable by the fact that a third individual partaking of the meal was unaffected. Thermostability of amanita toxin was well demonstrated by its resistance to boiling and frying for almost an hour (at a maximum temperature of about 140° C), the silver-spoon test recommended by Atkinson (1900) proved a misleading and dangerous criterion by which to judge whether the "mushrooms" were safe or not, and, finally, *A. phalloides* was palatable and even pleasant to eat.

The long delay interval of nine and twelve hours respectively before the onset of symptoms emphasizes the important point made by Birch (1946), that in any case of mushroom poisoning an interval of eight hours or more between ingestion and symptoms should be regarded as diagnostic of *A. phalloides* poisoning. The severity of the gastrointestinal symptoms in the early stages of the illness contrasted with the surprisingly mild hepato-renal damage which took place later (see Table). The importance of eliminating factors in assisting recovery is indicated by the fact that the patient with the shorter silent interval and the more severe and prolonged diarrhoea and vomiting sustained less liver damage than his colleague, whose condition in the early stages was considered the more satisfactory. In addition, poisoning by *A. phalloides* combined with other species of fungus has a better prognosis than poisoning by *A. phalloides* alone, the reason for this being that other types of fungus often cause earlier diarrhoea (Vander Veer and Farley, 1935).

### Summary and Conclusions

Mushroom poisoning due to *Amanita phalloides* in two German prisoners of war is described. Both patients recovered.

The severity of the gastro-intestinal symptoms in the early stages of the illness contrasted with the mildness of the delayed hepato-renal damage.

The delayed effects of poisoning were more severe in the patient with the longer silent period before the onset of symptoms and with the less pronounced and protracted diarrhoea and vomiting.

The ability of the gastro intestinal tract to eliminate the toxin of *A. phalloides* and the thoroughness with which this elimination is assisted by early and efficient gastric and colonic lavage, are regarded as factors of the greatest importance in determining recovery.

My thanks are due to the Director General of Medical Services for permission to publish this paper and to Professor John McMichael for his helpful criticism and advice. The invaluable assistance of Squadron Leader Meredith Brown, who identified specimens of fungus, and the keen co-operation of Flight-Lieut. E. R. Arnold, who was responsible for the care of the patients and for carrying out treatment, are much appreciated.

## TREATMENT OF GENU VALGUM

### THE DISCARDED IRON

BY

H. A. BRITTAIN, M.Ch., F.R.C.S.

Senior Orthopaedic Surgeon Norfolk and Norwich Hospital

The psychological effect, both on child and on parent, of wearing irons is usually unpleasant. There are occasionally exceptional people, like the late President of the United States, who achieve superiority in spite of their disability. That is possibly because the essential necessity for wearing irons has been revealed to them and they have been told that irons are necessary for progression or even existence.

Every orthopaedic surgeon who has served during the war must have experienced a thrill on his return to civilian practice on seeing as a young adult apparently cured a child who had been under his treatment five years previously. He may be labouring in the fields, she may be soignée with lipstick and rouge. Yet if treatment has extended over several years it is always easy to detect in these patients a difference from others. An intangible shyness or barrier is present. It might be called an inferiority complex, but it is a sequel of prolonged immobilization, with which social segregation is invariably associated. This result may be regrettable, but it is tempered by the fact that such treatment has been inescapable.

In quite a different category is the child who has to wear an instrument which proclaims to all that he or she is a "cripple," though in truth such an instrument is merely corrective and not essential. Here, leading all the rest, is the knock-knee iron or brace, an appliance of very doubtful value.

This paper is based on impressions derived from the treatment of 8,000 cases of genu valgum treated over a period of 15 years, and has been prompted by seeing children returned to East Anglia after evacuation to other parts of England where treatment was carried out with knock-knee braces and without appreciable results.

### Aetiology

Jones and Lovett (1929) describe knock-knee under the heading of rickets. They, however, stress that rickets is not the only cause of knock-knee, and mention tuberculosis of the knee-joint and infantile paralysis as well as traumas in the neighbourhood of the knee-joint with malposition and epiphyseal injury. "Loose knees" in children are also mentioned, and I wish to emphasize these as being the chief cause. McMurray (1943) says "This very common deformity begins as a rule in early childhood, following on rickets," and ten lines later on he states "As a rule, deformity is due to this overgrowth of the inner side of the femur, the alignment and shape of the tibia remaining normal." Mereer (1943) states "The deformity of knock-knee develops, as a rule, in early childhood, and is almost invariably due to rickets."

Few orthopaedic surgeons now believe that rickets is the commonest cause of knock-knee, yet this claim holds pride of place in the three textbooks mentioned. I think that knock-knee is due to (1) laxity of ligaments or loose knees, as mentioned by Jones and Lovett (1929), (2) quadriceps insufficiency, and (3) the child being overweight.

It may be argued that if the knee is loose why does genu valgum not occur at the knee instead of genu valgum? The femora are much wider apart at the level of the great trochanters, and slope inwards towards the knee, so that the tendency is normally to valgus. Furthermore, the external lateral ligament of the knee is a thick and very strong structure, reinforced by the ilio-tibial band, and

The Ministry of Health has issued two leaflets explaining how to get dental treatment or sight tests and spectacles under the National Health Service. Members of the public can get copies of them from the offices of the executive councils (address from any post office), at local offices of the Ministry of National Insurance, and at various other centres, such as citizens advice bureaux.

and daily for the next three days. On each occasion lavage was continued until the return was clear. This involved as much as three gallons of fluid during the early part of treatment. Two ounces (57 cc) of 50% magnesium sulphate were left in the stomach. The effect of lavage produced an immediate and striking diminution of vomiting and diarrhoea, which ceased in the case of J. W. after the first treatment.

On Sept 14, 5% glucose in normal saline, four to five litres in 24 hours, intravenously, was begun, this was continued for four days, together with 15 units of soluble insulin and 10 mg of vitamin K four-hourly in an attempt to prevent or minimize liver damage, which was fully anticipated. Apart from ice to suck, all fluid requirements were met by parenteral administration. Atropine 1/100 gr (0.65 mg) and morphine 1/4 gr (16 mg) were prescribed to control restlessness and pain during the first three days.

On the sixth day unlimited glucose drinks and small quantities of citrated milk were substituted for the intravenous drip, but four-hourly insulin injections, combined with vitamin K and vitamin B<sub>1</sub> 12,000 units and 10 ml of 10% solution of calcium gluconate parenterally, were continued for a further forty-eight hours. A light diet rich in protein and carbohydrate was then prescribed and steadily increased until discharge from hospital on Oct 21, when the patients were taking a normal diet.

#### Clinical Course of Case 1 (H. W.)

Although gastric and colonic lavage decreased the frequency and severity of vomiting and diarrhoea, both persisted until the evening of the third day, when these symptoms gave way to complaints of upper abdominal pain. At this time the patient was unduly drowsy and lethargic. Examination revealed tenderness under the right costal margin, but the liver was not found to be enlarged. On the fourth day definite jaundice of the sclerotics was noted but the skin was normal in colour. The urine, small in amount, was dark amber and concentrated. The patient, however, felt much better, drowsiness was less marked and he was more alert, nor was there any complaint of abdominal pain or sign of liver enlargement. Clinical improvement from this point was rapid despite an intermittent pyrexia, which reached 102° F (38.9° C) on Sept 17 and persisted with gradual defervescence until Sept 27. All signs of jaundice had cleared by Sept 21, and urinary output, which had previously been unsatisfactory, rapidly improved.

**Laboratory Investigations**—Sept 14—Urine NAD. Sept 17—Blood Hb, 94% (Sahli), RBC, 4,280,000 WBC, 5,400 per c mm (polymorphs 77% lymphocytes 20% monocytes 3%). Urine Urobilinogen +, albumin and sugar nil, no deposit. Sept 18—Total plasma proteins 5.5 g per 100 ml, albumin-globulin ratio, 1.6:1. Oct 2—Electrocardiogram Physiological, no evidence of bundle-branch block (a feature reported by Hyman, 1928). Oct 4—BSR 35 mm in first hour (Westergren). Oct 5—Total plasma proteins 6.5 g per 100 ml, albumin-globulin ratio, 5:1. Oct 7—Serum bilirubin Less than 0.5 mg per 100 ml. Oct 17—BSR 14 mm in first hour (Westergren).

#### Clinical Course of Case 2 (J. W.)

On the second day after the first gastric and colonic lavage, for which three gallons (13.64 litres) were required, the patient felt more comfortable, while vomiting and diarrhoea ceased completely from this time. The patient still complained of pain under the right costal margin, but there was no jaundice or evidence of hepatic enlargement.

The condition appeared to have improved on the third day despite pyrexia to 101.6° F (38.7° C). Apart from superficial ulcers of lips and tongue there were no complaints, and the patient felt much better. Clinical examination was negative. Anuria, however, persisted throughout the day, and in the evening his condition rapidly deteriorated. He complained of generalized aching pain of sudden onset and severe right-sided upper abdominal pain, requiring morphine for relief. A bowel action, consisting of a very pale stool, was accompanied by passage of a few ounces of dark amber urine.

On the fourth day, after a noisy restless night when morphine and atropine had to be administered, the patient became more restless and very drowsy, although rousable. His chief complaint was severe abdominal pain. Jaundice of sclerotics and skin, although not deep, was obvious, and pruritus was troublesome. No haemorrhage or petechiae were seen. ## TREATMENT OF GENU VALGUM

### THE DISCARDED IRON

BY

H A BRITAIN, MCh, FRCS

Senior Orthopaedic Surgeon Norfolk and Norwich Hospital

The psychological effect, both on child and on parent, of wearing irons is usually unpleasant. There are occasionally exceptional people, like the late President of the United States, who achieve superiority in spite of their disability. That is possibly because the essential necessity for wearing irons has been revealed to them and they have been told that irons are necessary for progression or even existence.

Every orthopaedic surgeon who has served during the war must have experienced a thrill on his return to civilian practice on seeing as a young adult apparently cured a child who had been under his treatment five years previously. He may be labouring in the fields, she may be soignée with lipstick and rouge. Yet if treatment has extended over several years it is always easy to detect in these patients a difference from others. An intangible shyness or barrier is present. It might be called an inferiority complex, but it is a sequel of prolonged immobilization, with which social segregation is invariably associated. This result may be regrettable, but it is tempered by the fact that such treatment has been inescapable.

In quite a different category is the child who has to wear an instrument which proclaims to all that he or she is a "cripple," though in truth such an instrument is merely corrective and not essential. Here, leading all the rest, is the knock-knee iron or brace, an appliance of very doubtful value.

This paper is based on impressions derived from the treatment of 8,000 cases of genu valgum treated over a period of 15 years, and has been prompted by seeing children returned to East Anglia after evacuation to other parts of England where treatment was carried out with knock-knee braces and without appreciable results.

### Aetiology

Jones and Lovett (1929) describe knock-knee under the heading of rickets. They, however, stress that rickets is not the only cause of knock-knee, and mention tuberculosis of the knee-joint and infantile paralysis as well as fractures in the neighbourhood of the knee-joint with malposition and epiphyseal injury. "Loose knees" in children are also mentioned, and I wish to emphasize these as being the chief cause. McMurray (1943) says "This very common deformity begins as a rule in early childhood, following on rickets," and ten lines later on he states "As a rule, deformity is due to this overgrowth of the inner side of the femur, the alignment and shape of the tibia remaining normal." Mercer (1943) states "The deformity of knock-knee develops, as a rule, in early childhood, and is almost invariably due to rickets."

Few orthopaedic surgeons now believe that rickets is the commonest cause of knock-knee, yet this claim holds pride of place in the three textbooks mentioned. I think that knock-knee is due to (1) laxity of ligaments or loose knees, as mentioned by Jones and Lovett (1929), (2) quadriceps insufficiency, and (3) the child being overweight.

It may be argued that if the knee is loose why does genu varum not occur at the knee instead of genu valgum? The femora are much wider apart at the level of the great trochanters, and slope inwards towards the knee, so that the tendency is normally to valgus. Furthermore, the external lateral ligament of the knee is a thick and very strong structure, reinforced by the ilio-tibial band, and

The Ministry of Health has issued two leaflets explaining how to get dental treatment or sight tests and spectacles under the National Health Service. Members of the public can get copies of them from the offices of the executive councils (address from any post office), at local offices of the Ministry of National Insurance, and at various other centres, such as citizens' advice bureaux.

virtually unstretchable. The internal lateral ligament is a broad thin sheet, and inserted into it is the vastus internus, a muscle which always suffers in any lesion of the knee and, according to Smillie, contracts only in the last 10 to 15 degrees of extension. In a child whose muscles are incapable of supporting the weight-bearing joints adequately there is probably a generalized quadriceps insufficiency, and on clinical examination this is usually most pronounced in the vastus internus, with consequent stretching of the internal lateral ligament. It is much more common to find children overweight since the war, possibly because the diet has contained more carbohydrates—starch without stiffening. Lynx-eyed medical officers of health send to our clinics many children aged 2 with 1 in (2.5 cm) of genu valgum. They come so often that it seems that no child aged 2 can be without one inch of genu valgum. This genu valgum is entirely due to laxity of ligaments, and no bony deformity is present as yet.

In my opinion, to say that such a deformity is due to rickets is not true, but when these children are sent to us untreated at the age of 4 or 6 their femora have grown into a valgus deformity because of laxity of the internal lateral ligament and the effect of weight-bearing, and as a result there has been overgrowth of the internal condyle of the femur. I consider that this is the true aetiology and that seldom is rickets the cause.

### Diagnosis

The usual method of examining the amount of genu valgum is to measure the intermalleolar distance. This may be a fictitious assessment. (1) because if the angle between the femur and tibia is to remain the same the distance between the malleoli must increase with growth, and (2) one can seldom exert a pressure accurately to equal the weight of the child without causing pain. Therefore not only should the intermalleolar distance be assessed with the child both sitting and standing, but the angle between the femur and the tibia should be noted on each side.

### The Knock-knee Brace

Jones and Lovett (1929) devote at least one page to a description of the knock-knee brace, and McMurray (1943), dealing with moulding, says "As with all rickety deformities, continued moulding is often successful in correcting the knock-knee in the acute stages of the disease, and in a large proportion of children so treated operative correction is unnecessary. If, after moulding, the remaining deformity is slight, a knock-knee iron should be used to maintain and complete the correction. The iron should be removed only when correction has been obtained, or when it is obvious that further improvement is impossible." One may comment that if there is bony deformity moulding cannot help, and if there are loose knees moulding will only make them looser.

Mercer (1943) states that considerable improvement, if not cure, can be obtained by manipulation, and also mentions the Jones walking knock-knee brace.

### Treatment

About one patient a year requires operation, certainly not more, wedging of the shoes is carried out in every case, and night splints in the majority. "La vérité c'est dans les nuances," said Voltaire, and this apothegm can be applied to every branch of orthopaedics or surgery or medicine.

#### Wedging the Shoes

The shoe is wedged  $\frac{3}{16}$  in (0.47 cm) on the inner side, sole, and heel. When I returned to civilian practice I was impressed by the number of children who had not improved after having only the shoe heels wedged. If the wedge can

be incorporated in the upper so much the better. The mothers must be told how important it is that the children wear their wedged shoes all day. A "gramophone record" is quoted, based on a verbal communication from Watson-Jones, and here one cannot stress too much how important it is that the surgeon himself speaks to the mother as follows:

'Your child has knock-knees now. If she is not treated she may grow up with them. Apart from looking unsightly, they may become painful when she grows older. By seeing that her shoes are wedged now you can make sure that she will get better, but she must wear the shoes all the time. That is to say, she must put on her shoes before she gets out of bed, she must walk to her bath in them, and she must not stand up in her bath. If you bring her to see me in six months' time and she has not improved, I will tell you that she has been walking without her wedged shoes.'

Cleats or studs may be necessary to keep the wedges constant. As a rule three studs on the outer side of the heel are sufficient.

#### Night Splints

Night splints produce quicker results than wedging of the shoes alone, but are not prescribed for small amounts of deformity or for fretful children as they may interfere with sleep. Simple gutter splints suffice for small degrees of deformity in young children. In older children with a greater degree we have found the night splints described by Lloyd (1939, 1943) to be excellent, because they do not rotate in the longitudinal axis and therefore remain accurately in the corrective position. Lloyd's night splint (Fig 1) is based on the mechanics of the Jones knock-knee brace. Fig 2 shows the knee braced back into full extension by bandaging the limb to the smaller posterior piece. The longer portion of the splint is then locked into position by sliding the tubes A and B over the rods *a* and *b*, and lateral pressure is put on the knee by continuing the bandage round the lateral part of the splint. The bandage is taken well above and below the knee, but the greatest pressure is over the knee area.

FIG 1

FIG 2

FIG 3

## Osteotomy

An osteotomy is seldom necessary. It is carried out, however, in two circumstances.

(a) *For the Child who is Resistant to Treatment*—These patients are generally over the age of 10, with a neglected deformity and 4 in (10 cm) of intermalleolar separation. The osteotomy is performed through a window in a bilateral plaster-of-Paris spica. A line is drawn on the anterior surface of the plaster through the long axis of the limb, an angle being made at the site of the proposed osteotomy. The operation is carried out from the outer side, the plaster first having been cut through two thirds of its circumference, the inner third remaining intact. The plaster is straightened until the angle no longer exists and the thigh and the shin make a straight line. The plaster is then completed. By this method the possibility of gross displacement of fragments is minimized and a meticulously perfect position is assured.

(b) *For Osteo-arthritis in Patients over the Age of 40*—Knock-knees become arthritic, and this is a point which should be stressed to mothers who are reluctant to have their children's shoes wedged and who consider the application of night splints tiresome and unnecessary. Osteo-arthritis occurs because the outer side of the joint is taking all the weight and the inner side is comparatively idle. In an adult the osteotomy is carried out by linear cuts with an electric saw through the femur just above the knee, and the femur is moulded into the position of correction. I have performed three osteotomies for osteo-arthritis due to excessive knock-knee in patients over the age of 50, with relief of pain and apparently good function.

McMurray suggests an osteotomy through the tibia. Of this I have no experience. Nevertheless I would hesitate to perform a high tibial osteotomy nowadays because of my experience of occasional severe vascular complications after fractures in this region.

The following table gives a working basis for treatment.

2 in (5 cm) G V below age of 4	Wedge sole and heel only
2 in G V above age of 4	Wedge sole and heel, night splints
More than 2 in G V below age of 4	Wedge sole and heel, night splints
More than 2 in G V above age of 5	Wedge sole and heel, night splints
4 in (10 cm) G V above age of 7	Osteotomy

This plan may require modification when deformity increases in spite of these conservative measures. That occurs but rarely, and when it does I carry out an osteotomy at an earlier age.

During a recent visit to America I was impressed by the intermediate results of stapling—i.e., the application of staples to control the growth of the lower end of the femur (Blount, 1944). This appears to be a simple, tidy method, less tedious than the prolonged wearing of wedged shoes and night splints, and seems to have a definite place in the treatment of children aged 14–15, in whom shoes have little corrective action and in whom there may be intolerance of night splints. This treatment is, however, *sub judice*.

## Conclusions

The psychological effect of knock-knee irons is bad. This is one of the reasons, and an important one, why they should not be used in the treatment of genu valgum.

Genu valgum is seldom caused by rickets. In a large proportion of patients it is due to laxity of ligaments, to quadriceps insufficiency, and to the child being overweight.

Wedged shoes and night splints are sufficient treatment in the majority of cases. Occasionally a supracondylar osteotomy of the femur is desirable in both children and adults.

I wish to thank Mr Eric I Lloyd and the Editor of the *British Medical Journal* by whose permission the illustrations are reproduced. The makers of the splints are Messrs Beckett and Bird, Bentunck Street, W 1.

## A CASE OF SKIN SENSITIZATION TO STREPTOMYCIN

BY

C STRINGFELLOW, MD

Registrar Department of Medicine University of Leeds

The use of streptomycin is restricted at present in this country. The drug is soon to be produced in greater quantities, however, and the time is not long distant when it will become generally available and in common use. It is considered of interest, therefore, to publish details of the following case of sensitization to streptomycin.

## Case History

Sister R W had had the care of six cases of tuberculous meningitis for four months, during the whole of which time she gave about 40 intramuscular injections of streptomycin a week. The strength of the solution varied between 200 and 500 mg per ml and at each injection some soiling of the fingers and hands with the solution was almost unavoidable. At no time did she wear protective rubber gloves.

She was well and did not complain of symptoms during the first three months of exposure, but after this period there was some irritation at night. The little and ring fingers of the right hand and the web between these two fingers were first affected. Two weeks later a similar irritation was noticed on the left hand. At about the same time an eruption suddenly appeared in the flexures of both elbows, and swelling and itching of both eyelids became apparent. There was some rhinitis with a thin watery discharge, and the patient felt generally unwell, but there was no fever.

On examination the contiguous and dorsal surfaces of the little and ring fingers of both hands showed thickening of the skin, with superficial desquamation and fissuring, and there was a slight serous discharge from the lesion. The skin of the web of the affected fingers was reddened, with pin-point papules and a few minute colourless vesicles, some of which had ruptured and discharged a little fluid. A similar fine papular and vesicular eruption affected the flexures of both elbows over an area of 6 by 4 in (15 by 10 cm). The skin of the eyelids was oedematous, dusky in colour, and showed a fine desquamation. Nothing further abnormal was discovered on full routine examination.

## Patch-testing

Patch tests on the patient and all other members of the nursing staff handling streptomycin were carried out in the following way. 0.2 ml of 1.5 solution of streptomycin calcium chloride complex (Merck), containing 1 g of active base in 1.3 g of substance, was used, drawn from the same batch of drug as is in current use in the treatment of cases in this centre. Sterile water was the solvent. The solution was spread on a single layer of gauze 1 in (2.5 cm) square, and the whole was covered with a piece of jaconet, which was held in place with zinc-oxide plaster. A control patch consisting of gauze, jaconet, and plaster was used in each case. The skin was not cleaned as a preliminary. The patch was left in place for 24 hours, and the area was examined at the time of its removal and 24 and 48 hours later.

The patient and seven other nurses who had administered the drug for periods of between one and a half and five months were thus observed. A control group of seven volunteers who had not been in contact with the drug were also tested. In all

**Osteotomy**

An osteotomy is seldom necessary. It is carried out, however, in two circumstances.

(a) *For the Child who is Resistant to Treatment*—These patients are generally over the age of 10, with a neglected deformity and 4 in (10 cm) of intermalleolar separation. The osteotomy is performed through a window in a bilateral plaster-of-Paris spica. A line is drawn on the anterior surface of the plaster through the long axis of the limb, an angle being made at the site of the proposed osteotomy. The operation is carried out from the outer side, the plaster first having been cut through two thirds of its circumference, the inner third remaining intact. The plaster is straightened until the angle no longer exists and the thigh and the shin make a straight line. The plaster is then completed. By this method the possibility of gross displacement of fragments is minimized and a meticulously perfect position is assured.

(b) *For Osteo-arthritis in Patients over the Age of 40*—Knock-knees become arthritic, and this is a point which should be stressed to mothers who are reluctant to have their children's shoes wedged and who consider the application of night splints tiresome and unnecessary. Osteo-arthritis occurs because the outer side of the joint is taking all the weight and the inner side is comparatively idle. In an adult the osteotomy is carried out by linear cuts with an electric saw through the femur just above the knee, and the femur is moulded into the position of correction. I have performed three osteotomies for osteo-arthritis due to excessive knock-knee in patients over the age of 50, with relief of pain and apparently good function.

McMurray suggests an osteotomy through the tibia. Of this I have no experience. Nevertheless I would hesitate to perform a high tibial osteotomy nowadays because of my experience of occasional severe vascular complications after fractures in this region.

The following table gives a working basis for treatment.

2 in (5 cm) G V below age of 4	Wedge sole and heel only
2 in G V above age of 4	Wedge sole and heel, night splints
More than 2 in G V below age of 4	Wedge sole and heel, night splints
More than 2 in G V above age of 5	Wedge sole and heel, Lloyd's night splints
4 in (10 cm) G V above age of 7	Osteotomy

This plan may require modification when deformity increases in spite of these conservative measures. That occurs but rarely, and when it does I carry out an osteotomy at an earlier age.

During a recent visit to America I was impressed by the intermediate results of stapling—i.e., the application of staples to control the growth of the lower end of the femur (Blount, 1944). This appears to be a simple, tidy method, less tedious than the prolonged wearing of wedged shoes and night splints, and seems to have a definite place in the treatment of children aged 14–15, in whom shoes have little corrective action and in whom there may be intolerance of night splints. This treatment is, however, *sub judice*.

**Conclusions**

The psychological effect of knock-knee irons is bad. This is one of the reasons, and an important one, why they should not be used in the treatment of genu valgum.

Genu valgum is seldom caused by rickets. In a large proportion of patients it is due to laxity of ligaments, to quadriceps insufficiency, and to the child being overweight.

Wedged shoes and night splints are sufficient treatment in the majority of cases. Occasionally a supracondylar osteotomy of the femur is desirable in both children and adults.

I wish to thank Mr Eric I Lloyd and the Editor of the *British Medical Journal* by whose permission the illustrations are reproduced. The makers of the splints are Messrs Beckett and Bird, Bentinck Street, W1.

## A CASE OF SKIN SENSITIZATION TO STREPTOMYCIN

BY

**C STRINGFELLOW, M.D.***Registrar Department of Medicine University of Leeds*

The use of streptomycin is restricted at present in this country. The drug is soon to be produced in greater quantities, however, and the time is not long distant when it will become generally available and in common use. It is considered of interest, therefore, to publish details of the following case of sensitization to streptomycin.

**Case History**

Sister R. W. had had the care of six cases of tuberculous meningitis for four months, during the whole of which time she gave about 40 intramuscular injections of streptomycin a week. The strength of the solution varied between 200 and 500 mg per ml and at each injection some soiling of the fingers and hands with the solution was almost unavoidable. At no time did she wear protective rubber gloves.

She was well and did not complain of symptoms during the first three months of exposure, but after this period there was some irritation at night. The little and ring fingers of the right hand and the web between these two fingers were first affected. Two weeks later a similar irritation was noticed on the left hand. At about the same time an eruption suddenly appeared in the flexures of both elbows, and swelling and itching of both eyelids became apparent. There was some rhinitis with a thin watery discharge, and the patient felt generally unwell, but there was no fever.

On examination the contiguous and dorsal surfaces of the little and ring fingers of both hands showed thickening of the skin, with superficial desquamation and fissuring, and there was a slight serous discharge from the lesion. The skin of the web of the affected fingers was reddened, with pin-point papules and a few minute colourless vesicles, some of which had ruptured and discharged a little fluid. A similar fine papular and vesicular eruption affected the flexures of both elbows over an area of 6 by 4 in (15 by 10 cm). The skin of the eyelids was oedematous, dusky in colour, and showed a fine desquamation. Nothing further abnormal was discovered on full routine examination.

**Patch-testing**

Patch tests on the patient and all other members of the nursing staff handling streptomycin were carried out in the following way. 0.2 ml of 1.5 solution of streptomycin calcium chloride complex (Merck), containing 1 g of active base in 1.3 g of substance, was used, drawn from the same batch of drug as is in current use in the treatment of cases in this centre. Sterile water was the solvent. The solution was spread on a single layer of gauze 1 in (2.5 cm) square, and the whole was covered with a piece of jaconet, which was held in place with zinc oxide plaster. A control patch consisting of gauze, jaconet, and plaster was used in each case. The skin was not cleaned as a preliminary. The patch was left in place for 24 hours, and the area was examined at the time of its removal and 24 and 48 hours later.

The patient and seven other nurses who had administered the drug for periods of between one and a half and five months were thus observed. A control group of seven volunteers who had not been in contact with the drug were also tested. In all

virtually unstretchable. The internal lateral ligament is a broad thin sheet, and inserted into it is the vastus internus, a muscle which always suffers in any lesion of the knee and, according to Smillie, contracts only in the last 10 to 15 degrees of extension. In a child whose muscles are incapable of supporting the weight-bearing joints adequately there is probably a generalized quadriceps insufficiency, and on clinical examination this is usually most pronounced in the vastus internus, with consequent stretching of the internal lateral ligament. It is much more common to find children overweight since the war, possibly because the diet has contained more carbohydrates—starch without stiffening. Lynx-eyed medical officers of health send to our clinics many children aged 2 with 1 in (2.5 cm) of genu valgum. They come so often that it seems that no child aged 2 can be without one inch of genu valgum. This genu valgum is entirely due to laxity of ligaments, and no bony deformity is present as yet.

In my opinion, to say that such a deformity is due to rickets is not true, but when these children are sent to us untreated at the age of 4 or 6 their femora have grown into a valgus deformity because of laxity of the internal lateral ligament and the effect of weight-bearing, and as a result there has been overgrowth of the internal condyle of the femur. I consider that this is the true aetiology and that seldom is rickets the cause.

### Diagnosis

The usual method of examining the amount of genu valgum is to measure the intermalleolar distance. This may be a fictitious assessment (1) because if the angle between the femur and tibia is to remain the same the distance between the malleoli must increase with growth, and (2) one can seldom exert a pressure accurately to equal the weight of the child without causing pain. Therefore not only should the intermalleolar distance be assessed with the child both sitting and standing, but the angle between the femur and the tibia should be noted on each side.

### The Knock-knee Brace

Jones and Lovett (1929) devote at least one page to a description of the knock-knee brace, and McMurray (1943), dealing with moulding, says "As with all rickety deformities, continued moulding is often successful in correcting the knock-knee in the acute stages of the disease, and in a large proportion of children so treated operative correction is unnecessary. If, after moulding, the remaining deformity is slight, a knock-knee iron should be used to maintain and complete the correction. The iron should be removed only when correction has been obtained, or when it is obvious that further improvement is impossible." One may comment that if there is bony deformity moulding cannot help, and if there are loose knees moulding will only make them looser.

Mercer (1943) states that considerable improvement, if not cure, can be obtained by manipulation, and also mentions the Jones walking knock-knee brace.

### Treatment

About one patient a year requires operation, certainly not more, wedging of the shoes is carried out in every case, and night splints in the majority. "La vérité c'est dans les nuances," said Voltaire, and this apothegm can be applied to every branch of orthopaedics or surgery or medicine.

#### Wedging the Shoes

The shoe is wedged 3/16 in (0.47 cm) on the inner side, sole, and heel. When I returned to civilian practice I was impressed by the number of children who had not improved after having only the shoe heels wedged. If the wedge can

be incorporated in the upper so much the better. The mothers must be told how important it is that the children wear their wedged shoes all day. A "gramophone record" is quoted, based on a verbal communication from Watson-Jones, and here one cannot stress too much how important it is that the surgeon himself speaks to the mother as follows:

"Your child has knock-knees now. If she is not treated she may grow up with them. Apart from looking unsightly, they may become painful when she grows older. By seeing that her shoes are wedged now you can make sure that she will get better, but she must wear the shoes all the time. That is to say, she must put on her shoes before she gets out of bed, she must walk to her bath in them, and she must not stand up in her bath. If you bring her to see me in six months' time and she has not improved, I will tell you that she has been walking without her wedged shoes."

Cleats or studs may be necessary to keep the wedges constant. As a rule three studs on the outer side of the heel are sufficient.

#### Night Splints

Night splints produce quicker results than wedging of the shoes alone, but are not prescribed for small amounts of deformity or for fretful children as they may interfere with sleep. Simple gutter splints suffice for small degrees of deformity in young children. In older children with a greater degree we have found the night splints described by Lloyd (1939, 1943) to be excellent, because they do not rotate in the longitudinal axis and therefore remain accurately in the corrective position. Lloyd's night splint (Fig 1) is based on the mechanics of the Jones knock-knee brace. Fig 2 shows the knee braced back into full extension by bandaging the limb to the smaller posterior piece. The longer portion of the splint is then locked into position by sliding the tubes A and B over the rods *a* and *b*, and lateral pressure is put on the knee by continuing the bandage round the lateral part of the splint. The bandage is taken well above and below the knee, but the greatest pressure is over the knee area.

## Reviews

### STATISTICAL METHODS

*Statistical Methods in Research and Production* With Special Reference to the Chemical Industry Edited by Owen L. Davies, M Sc, Ph D (Pp 292 28s) London and Edinburgh Oliver and Boyd

This volume is the work of seven contributors, and, Lord McGowan states in a foreword, the first of a series of scientific and technical handbooks which Imperial Chemical Industries intend to publish with the aim of making generally available the important information accumulated as a result of the company's manufacturing experience and research. While the company hopes that these publications will be of particular help to industrialists and technicians in industry, this book should certainly be more widely useful than that. Its approach is, naturally, through problems encountered in the chemical industry, and its examples are mainly of the applications of statistical methods in that field. But many research workers with other interests will undoubtedly find it of assistance in learning and applying statistical techniques to any type of data, particularly, it would be fair to add, those who either already have some grounding in statistical theory and methodology or are not perturbed by algebraical symbols. The arithmetician will be aided by the numerous examples that are fully worked out (and upon which—an essential step—he can practise), but much of the discussion and the approach to the arithmetical processes are centred around mathematical expressions.

The book contains chapters on frequency distributions, averages and measures of dispersion, the customary tests of significance, the analysis of variance, regressions and correlation, contingency tables and the chi-squared test, general problems of sampling, control charts, and prediction and specification. A useful glossary of statistical terms is included, and also a list of the statistical and mathematical symbols in general use with guidance on their type setting. The usual tables of statistical functions are given at the end—the normal, chi-squared  $t$  variance ratio, binomial and Poisson distributions, the significance levels for the correlation coefficient, and control-chart limits for the average and range. It is clear that the authors have taken great pains over the setting of their text, arithmetical examples, and algebra, and in these austere days it is a pleasure to handle a book so beautifully produced.

A BRADFORD HILL

### PSYCHO-ANALYSIS AND CHILDREN

*The Psychoanalytic Study of the Child* Volume II 1946 Edited by Anna Freud, Willie Hoffer, M D, Ph D, L R C P, Edward Glover M D, et al (Pp 424 30s) London Imago Publishing Co

It is impossible to do justice to this volume in a short review, so that the reader is advised to get hold of a copy if his interest is in child psychiatry or in psychological theory. Much that is both interesting and clinically important is discussed, and the continued work of the Imago Publishing Company is justified by it. "Problems of Child Development" include a theoretical study of psychic structure, a study of laughter, a further contribution from Mrs Burlingham on twins, and a study of the pre-oedipal development of the male child. "Clinical Problems" include articles on feeding disturbances by Anna Freud, the psychogeneses of tic and of reading disabilities, the analysis of a child with night terrors, and clinical observation of enuretics, a valuable description of psychosis in childhood by Elizabeth Galeerd and comments on the diaries of schizophrenics by Willie Hoffer. "Guidance Work" and "Problems of Education and Sociology" are other headings to sections, and there is a historical note on J B Felix Descuret (1795-1872).

Only one article can be picked out for detailed comment, that by Rene A Spitz on what he calls anaclitic depression is chosen, because it involves consideration of Melanie Klein's concept of the depressive position in emotional development. Spitz makes a special point of disclaiming acceptance of this concept. The material of the article is excellent. The infants in an institution who had all been (unavoidably) separated from

their mothers at the age of 6-8 months were found to become depressed at 8-11 months. The author gives interesting clinical details.

Klein uses the term depressive position to describe an achievement of the human infant. If all goes well with the emotional development of any infant a stage is reached at which the infant recognizes the results of erotic and aggressive impulses and ideas, so that henceforth he is concerned, is able to feel responsibility and guilt. Only if this stage is achieved is deprivation liable to cause depression or, in the simplest case, mourning. Failure to arrive at, or regression from, this stage indicates a severe (psychotic) disturbance of emotional development, and results in the infant's showing the more primitive defences such as a disintegration of the personality, depersonalization, and loss of contact with reality. But Spitz writes: "Klein assumes that human beings are born with a finished and complete psychic structure." In fact, she does not.

It could be said of the depression observed and described by Spitz that these infants, through early contact with their own mothers and through their subsequent management in the institute, had gone forward in development sufficiently to be capable of becoming depressed, this being an indication of health, more seriously disturbed infants would have failed to achieve this clear depressive mood in reaction to loss. On the basis of an understanding of Klein's theory the author's observation that depression occurred only at 8-10 months is a useful contribution to the discussion of the theory, without such understanding his good clinical observations are wasted. It would be a pity if subsequent volumes must be marred by further uninformed references to Klein. The first volume contained a serious attack on Klein which was too biased to have an effect on scientific thought, but this article loses value through lack of understanding. It is urgently necessary that Klein's critics get to know what she is in fact saying.

D W WINNICOTT

### EMERGENCY SURGERY

*Emergency Surgery* By Hamilton Bailey, FRCS, FICS, FRSEd Part I Sixth edition To be issued in 5 parts (Pp 180, illustrated 21s) Bristol John Wright and Sons 1948

The sixth edition of Mr Hamilton Bailey's *Emergency Surgery* is appearing in five parts, of which we have recently received Part I. In size and arrangement it closely resembles one of the six parts of the third and last edition of the same author's highly successful book, *The Surgery of Modern Warfare*. Printing and binding difficulties are apparently still acute, and production in parts to a certain extent overcomes them.

In assessing the qualities necessary for the exacting practice of emergency surgery Mr Bailey rightly emphasizes physical fitness, mental alertness, and readiness at all times to attend to demands on his services as qualities as important to the surgeon as technical training and experience. However there is still a need for a guide book since emergency operations are so often performed by those beginning the practice of surgery. For many years such a guide was to be found in French in the *Traité de Chirurgie d'Urgence* of Felix Lejars, of Paris, who died in 1932 and in the translated English edition of the book by Mr W S Dickie of Middlesbrough. In more recent times Hamilton Bailey's book has met the same demand, and, now brought up to date in this new edition, it is, like all his well-known publications, an admirable production. The author has already achieved a world-wide reputation as a writer of surgical textbooks which are so well and clearly produced that certain of them have reached the "best seller" class—unusual enough among textbooks to be praise indeed.

In the first volume he discusses infusion and transfusion, shock, restoration of the patient in extremis while under anaesthesia, complications of operation such as burst abdomen, and intra-abdominal acute infective lesions such as appendicitis and salpingitis. Among aids to prevent phlebothrombosis he might have mentioned support of the Achilles tendons to keep the calf muscles free from pressure by the operating table, for there is incontrovertible evidence that it is in the calf veins that the condition begins and if the calves are immobile and lying on the table the vein walls are in apposition and free flow in them is impeded. In a balanced account of drainage, which

es save that of the patient both the patch and the control were negative. In the patient, at the end of 24 hours an erythematous eruption at the site was apparent, which later became oedematous and itched. The original skin lesions, which had by then almost disappeared following withdrawal from contact with the drug, showed a simultaneous exacerbation. Further patch tests were carried out with solutions of 1 10, 1 50, 1 100, 1 500, and 1 1,000. With the solutions of 1 10 and 1 50 a similar oedematous and erythematous lesion was observed at the site at the end of the examination period, and there was a similar exacerbation of the clinical manifestations in the original skin lesions. A papular erythematous eruption was seen with the weaker solutions, the lesion being minimal in the test to 1 1,000, and no general reaction was experienced. All the control patches were negative.

### Discussion

Strauss and Warring (1947) reported four similar cases among 12 nurses in contact with streptomycin. One developed symptoms after a month, whereas the other three required approximately three months' exposure before any changes were noticed. In all cases the eruption first showed upon the fingers, in two the flexures of the elbow were affected, and changes in the eyelids were noted in all four. The clinical development, the pattern of reaction, and the type of the eruption were strikingly similar to that in the present case. By patch-testing they detected two further cases of sensitization which had not hitherto shown clinical manifestations. They were able to patch-test their sensitized cases with a solution containing only 2% of impurities, and induced a similar lesion to that produced by a solution with as high a proportion of impurities as was used by ourselves. They conclude, therefore, that the sensitization is probably not due to the presence of impurities. For lack of material it was not possible to confirm their findings.

Crofton and Foreman (1948) described four cases of sensitization to streptomycin, the nurses concerned having been exposed to the drug for periods of between six weeks and six months. Oedema and itching of the eyes occurred in three of them, whilst in two cases the skin of the face was involved. The eruption on the hands and arms was similar to that in the present case. They carried out skin tests, using intradermal injections of 50  $\mu$ g of streptomycin hydrochloride dissolved in 0.1 ml of saline. Positive results were obtained in all four cases, and exacerbation of the original skin lesions occurred in three. The authors failed to detect similar skin sensitization in 30 other nurses who had been exposed to the drug.

The absence of reaction to a 1 5 solution in the other exposed personnel and the control volunteers in the present investigation suggests that the solution is not a primary irritant and that this eruption is a sensitization phenomenon. Considering the long period of exposure required before clinical signs become manifest, it seems reasonable to suppose that this sensitization is acquired. Further work is in progress in an attempt to elucidate this point.

### Summary

A case of skin sensitization to streptomycin in a nursing sister is reported.

Patch-testing of seven other exposed nurses failed to detect further sensitized cases.

Negative patch-tests in a control group suggest that the drug is unlikely to be a primary irritant.

It is considered probable that the sensitization is acquired.

My thanks are due to members of the Leeds Streptomycin Committee for their helpful advice and their permission to publish this case.

## Medical Memoranda

### Gangrene after Scorpion Sting

Scorpion sting causes pain and discomfort of only short duration and serious complications do not usually occur, though slight local necrosis has been seen in some cases. In rare cases, however, especially in children, death has been reported. In the following case gangrene of a finger occurred after a scorpion sting.

#### CASE REPORT

On Feb 13, 1947, a young healthy girl of about 17 was stung on the pulp of the right ring finger by a scorpion which was found and killed. This was followed immediately by the usual symptoms—namely, burning pain, tenderness, and swelling at the site of the sting and cold perspiration of the whole body. A few minutes later a blister appeared just proximal to the point of the sting and it soon spread to and round the middle of the second phalanx of the finger. Potassium permanganate crystals were applied to the point of the sting and a starch poultice to the blister. The latter was applied for about two hours with no effect on the blister, which

burst on the third day, leaving a raw surface underneath. As the tip of the finger was gradually getting dry and black she consulted a doctor on Feb 22, who advised cleaning the part with spirit and dusting it with 'cibazol'—acriflavine powder.

When I first saw her, on March 1, the tip of the finger was dry and black, and proximal to this was a discoloured area which was limited above by a demarcation line. When seen on March 10, the dry black area had extended to the demarcation line. (see illustration)

#### COMMENT

I could not find any reference to the occurrence of gangrene after scorpion sting in the literature on Indian scorpions. Dr. K. S. Mhaskar, joint author of *Indian Medical Research Memoir on Indian Scorpions* (1932, No. 24), writes in a personal letter that he never came across any case of gangrene after scorpion sting. S. Kubota (1918), however, has reported a case in which local necrosis occurred after a sting by a Manchurian scorpion (*Buthus martensi*). Nowak (1898) showed that when injected subcutaneously scorpion venom, like snake venom, may produce local necrosis.

In the above case the gangrene may have been produced by the action of substances applied locally or by the infection of the part. However, the local application of potassium permanganate to the point of the sting and the application of starch poultice to the blister were not such as to give rise to the production of gangrene in the finger. Infection also does not seem to be the causative factor, as the gangrene appeared to be of the dry type from the beginning. The production of gangrene therefore seems to be due to the action of the venom.

The variety of the scorpion concerned is not known, but it seems probable that the venom of a particular variety produces local necrosis. Though the occurrence of gangrene after scorpion sting might not be very common, the disability it causes should call for further research in this field.

SATURDAY AUGUST 21 1948

## STREPTOMYCIN IN USE

The number of publications reporting results of treatment with streptomycin is now swelling to a flood reminiscent of that produced by penicillin about four years ago. Whereas those from the United States deal with the subject in all its aspects, publications in this country are almost exclusively concerned with the treatment of tuberculosis, our more exiguous supplies having been chiefly devoted to this purpose. Notable among these is the recent report<sup>1</sup> of the Medical Research Council's Streptomycin in Tuberculosis Trials Committee, which decided, on its formation in September, 1946, to restrict the use of the drug to cases of tuberculous meningitis and miliary tuberculosis. The provision of facilities for treating these two forms of the disease has since been greatly extended by the Ministry of Health, and an adequate number of hospitals throughout the country, in addition to the centres operating under the M R C scheme, have been able to obtain streptomycin for this purpose during the past twelve months.

This report deals only with tuberculous meningitis, and is based on 105 cases followed up for a minimum of 4 months, of these patients 71 had died, 7 were stationary or deteriorating, and 27 were doing well. This low proportion of recoveries is unfortunately in accordance with the experience of most others, but some improvement may be expected if earlier diagnosis can be made and in any case when the most satisfactory schedule of treatment has been worked out. The effect of the duration of the disease on prognosis is abundantly clear in this series. Early diagnosis is by no means easy, and an article on the subject by Professor W S Craig which appears elsewhere in this issue (p 374) should be helpful to the family doctor who has not the advantage of laboratory facilities at his elbow. In patients in whom meningitis is accompanied by miliary tuberculosis, retinoscopy may help to confirm an early diagnosis. Professor R S Illingworth and Dr T Wright describe on page 365 of this issue a study of the occurrence of tubercles of the choroid in 65 patients falling into three categories. Tubercles were observed in 25 out of 42 cases of miliary tuberculosis, with or without meningitis, and changes in their appearance during treatment could be related to prognosis. The import-

ance of age is well seen in the M R C series in children under 3 the outlook is clearly much worse. It was also shown that intramuscular streptomycin alone is inadequate, intrathecal injections must also be given. Beyond this single fact it seems difficult to draw any conclusions about methods of administration. Among the successful results some patients had long and others quite short courses, treatment during the long courses was in some cases continuous and in others intermittent.

When to stop in an apparently successful case is the most difficult aspect of this problem. Debre and his colleagues, who recently described in the *Journal* a series of 118 cases treated in Paris, continued administration for as long as 10 months. At the other extreme, Glanzmann,<sup>2</sup> of Bern, reports an apparent success after only 15 days' vigorous treatment consisting of intramuscular and intrathecal injections, and he believes that in some cases this may be adequate. It has even been suggested that intramuscular injections are unnecessary. Ketelaer<sup>3</sup> gives a short general account of very favourable results obtained by two groups of Russian workers using intracisternal injections only, 12-20 being given during a period of 2 to 3 weeks. Another valuable contribution came from Oxford, where Sir Hugh Cairns and his colleagues<sup>4</sup> treated 18 cases, of whom 7 have died, 7 are doing well, and 4 are still under treatment. This series is notable for the great variety of surgical procedures used to facilitate both diagnosis and treatment. Ventricular puncture was carried out in all but two cases and streptomycin sometimes administered either by this route or continuously through a tube leading into the interpeduncular space.

At what intervals and for how long to administer streptomycin in treating either meningitis or other forms of tuberculosis is still unsettled. The present tendency is to prolong the interval between doses and somewhat to reduce the dose, but to continue treatment for an arbitrary period of 3 months or more. The best system cannot be rationally worked out until the action of streptomycin is better understood, particularly until it is known whether it has a predominantly bactericidal or bacteriostatic effect. The duration of effective treatment is closely connected with the problem of acquired bacterial resistance. In the M R C series little evidence of this was obtained, 19 out of 22 strains of *Myco tuberculosis* isolated from the cerebrospinal fluid after a month or more of treatment remained fully sensitive. These tests were made in the Dubos medium, and according to Fisher<sup>5</sup> this may give misleading results. He examined 20 strains isolated from patients after 12 weeks' treatment for pulmonary disease, 5 had acquired resistance and 15 apparently had not, but when these 15 were retested in another medium 6 were shown to be resistant. Subsequent study showed that Tween 80, a constituent of the Dubos medium, may enable a very low concentration to inhibit growth, whereas one a thousand times greater will fail to do so in its absence. Glycerin had a similar though less marked effect. Most studies of the acquisition of resistance have been made in cases of pulmonary disease, in which the repeated isolation of bacilli is relatively simple. It may possibly be misleading to apply these findings to other forms of the disease, but it certainly appears that the efficacy of treatment must often decline

opens with the statement that a cynic once condemned books because they do not tell us when to drain, the author would appear to be on the side of the drainers in doubtful cases but at the same time he well illustrates the harm which drainage tubes may do if used inadvisedly. Among his quotations from various surgeons he might have added the remark of still another surgeon who when asked why he had not drained the abdomen of a certain important person, remarked, 'There was nothing to drain'—sound reasoning enough.

If we may judge the whole from this first part this edition should be the best yet and more than ever appreciated by those for whom it has been written by one whose experience in this field is great, and who in the production of this account richly gives of it to his younger and less experienced colleagues.

LAMBERT ROGERS

### UNORTHODOX SYPHILOLOGY

*Syphilis* By Henri Mathias (Pp 722 600 francs) Paris Librairie Maloine 1947

This is a remarkable book to say that it is unorthodox would be an understatement. After an introduction in which the author points out that syphilis is one of the greatest enemies of the human race that it can and should be wiped out and that medical men should be better informed about it he discusses the subject in five parts. (1) Acquired syphilis, the causal organism, the progress of the disease, its prophylaxis and its relation to marriage and divorce. (2) treatment, with a criticism of current methods and attempts at shortening the time necessary for radical cure. (3) congenital syphilis. (4) the 'patho-genealogical' tree in the uncovering of congenital syphilis, and (5) a consideration of various problems connected with both the acquired and congenital forms.

It is not easy to understand why or for whom this book was written, presumably the author wished to air views which are not generally acceptable. It is not one for the student or general practitioner, though the dilettante experienced syphilologist may be interested and even amused by browsing over the 700 odd pages. It appears that the only remedy for early acquired syphilis is 'salvarsan' (the author dismisses penicillin in just over one page) given in a large number of small doses over a period of a year, in cases of congenital syphilis cyanide of mercury and bismuth may be given as well but must be injected intravenously.

The medical profession in general has no idea of the number of conditions for which congenital syphilis is directly or indirectly responsible, these range from psoriasis to haemophilia and from epilepsy to chronic appendicitis and include most of the ailments due to dysfunction of the ductless glands. The author evidently has the greatest contempt for the average syphilologist for refusing to use the gifts which God and science have given him—eyes to see congenital syphilis all around him and salvarsan. Perhaps the masterpiece of this work is the expression "Sterilisans magna sed in unum anno" (p 328).

T E OSMOND

The successive issues of the *Year Book of General Surgery* form milestones by which some estimate may be made of the advances in theory and practice as the years pass, they are also signposts to the general trend of surgical thought and investigation. Thus in the 1947 volume, edited by Dr Evarts A. Graham (H K Lewis, 21s), we find no less than 55 pages devoted to summaries of articles on the surgery of the blood vessels, and notices of eight papers relating to vagus section in the treatment of peptic ulceration but pyloro-duodenal sinuses, which during the war years attracted much attention, are now scantily represented by two articles only. As Dr Graham says in the introduction, surgical literature has returned largely to a peacetime plane after the large number of articles on military surgery in the preceding years. Work is being done in research laboratories again and many stimulating articles are appearing. He also makes a graceful reference to our own country "The British, despite most adverse conditions, are carrying on bravely. This is nothing new for them, as everybody knows. Most of their famous old hospitals were more or less badly damaged by the Nazi bombing, but by the use of make shifts of various kinds they are continuing to care for patients and to teach students." It is gratifying to read Dr Graham's opinion of our efforts. As usual we found it impossible to answer more than an insignificant number of the questions asked in the yearly 'quiz' on the dust-cover.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*The Stuff We're Made Of* By W O Kermack M A, D Sc, LL D, F R S, and P Eggleton D Sc F R S Ed 2nd ed (Pp 356 10s 6d) London Arnold 1948

An account of biochemistry including the vitamins and hormones for the general reader

*Transactions of the Fiftieth Annual Meeting of the American Laryngological, Rhinological and Otological Society* (Pp 587 No price) New York The Society 1946

Papers on a variety of ENT topics

*Proteins and Amino Acids in Nutrition* Edited by M Sahyun M A, Ph D (Pp 566 45s) London Chapman and Hall 1948

A collection of papers by various writers

*Identification of Tumors* By N Chandler Foot, M D (Pp 397 36s) London Lippincott 1948

A profusely illustrated account of the pathology of neoplasms

*The History of State Medicine in England* By Sir Arthur S MacNalty, K C B, M A, M D F R C P, F R C S (Pp 82 12s 6d) London Royal Institute of Public Health and Hygiene 1948

The FitzPatrick Lectures for 1946 and 1947 on State medicine in England from 1837 to 1919

*Disability Evaluation* By E D McBride, B S, M D F A C S 4th ed (Pp 667 72s) London Lippincott 1948

A textbook of the investigation and evaluation of industrial disabilities

*Treatment by Diet* By C J Barborka, B S M S, M D, D Sc F A C P 5th ed (Pp 784 60s) London Lippincott 1948

A textbook of diet therapy for the medical practitioner

*The Digestive Tract in Roentgenology* By J Buekstein, M D (Pp 889 100s) London Lippincott 1948

A textbook of x ray examination

*The Childless Marriage* By E F Griffith M R C S L R C P (Pp 206 8s 6d) London Methuen 1948

An account of the causes and treatment of sterility

*Dundee Royal Infirmary* By H J C Gibson (Pp 71 No price) Dundee Kidd 1948

Historical notes on the Infirmary

*Clinical Psychology* By C Berg M D, D P M (Pp 503 25s) London Allen and Unwin 1948

The psychoneuroses and their treatment, with illustrative case histories

*Calcium and Phosphorus in Foods and Nutrition* By H C Sheiman (Pp 176 15s) London Geoffrey Cumberlege 1948

A general account for students medical men and dietitians

*A Manual of Removable Partial Denture Design* By R Godfrey, D D S, M Sc (Pp 99 20s) London Geoffrey Cumberlege 1948

Intended for senior students of dentistry

*The Reach of the Mind* By J B Rhine (Pp 188 10s 6d) London Faber 1948

A brief account of experimental extra-sensory perception

*Textbook of Anaesthetics* By R J Minnitt M D, D A, and J Gilles, M C, M B, Ch B, F R C S Ed D A 7th ed (Pp 568 30s) Edinburgh Livingstone 1948

Much new material has been added to this edition

*Bacterial and Virus Diseases* By H J Paus M D, F R C P Ed, D P H (Pp 168 7s 6d) Edinburgh Livingstone 1948

A short account of the principles of immunology

regulations are pouring out from overworked Civil Servants who know nothing of practical detail," why does he not fix the blame for this on the Minister of Health, who refused to postpone the appointed day so that these matters could be considered more carefully once the profession had decided to co-operate with the Government in launching the new health service? The obsessional hurry of the Government to legislate is the cause of the sense of frustration Dr Bourne diagnoses as prevailing among medical men and women at the present time. Yet in spite of this the National Health Service has started off much more smoothly than anyone expected, and surely Dr Bourne is wearing blinkers when he suggests that the B M A should have had "plans ready in advance of the Ministry." He seems to have overlooked the fact that the B M A neither framed nor is operating the National Health Service Act. Dr Bourne continues to wield his *malleus maleficarum* by condemning the Association's proposals for the representation of the interests of consultants and specialists, and ignores the recent move made by the B M A in conjunction with the Royal Colleges and the Scottish Royal Corporations. These things are now being hammered out, and destructive criticism will be useful only in so far as it prepares the ground for constructive proposals.

That there should be unrest at this moment is, as has been stated, to be expected. Critical voices were heard at the Annual Representative Meeting at Cambridge, and have been echoed in letters to the *Journal*. The Winchester Division of the B M A has recently circulated a memorandum on the organization of the B M A in which it is interesting to find the exact opposite of Dr Bourne's criticism.

Members have been dismayed," the memorandum states, 'to find that while they have been engaged in the battle of general principles—capitation fee versus salary, etc.—negotiations of which we were not fully informed appear to have been proceeding over terms and conditions of service.' This underlines what has been stated above—

namely, that members of the B M A generally would have disapproved of negotiations over terms and conditions of service during the controversy on general principles. The Winchester memorandum criticizes the method of election to the B M A Council, the Representative Meetings ("These are a shambles—too many members discussing too many resolutions"), and the Headquarters staff for 'being out of touch with the rank-and-file of the profession,' although the extension of the work of the staff in the Divisions which the Council has lately arranged provides greatly increased opportunities for the periphery to make its views known at the centre. The fact that such criticisms are made is a healthy sign of an active interest by members in the welfare of the Association. It is good that they should come out into the open, for criticism that is stifled breeds resentment. With the introduction of the National Health Service the B M A will pass into a new phase of its existence and its organization will continue to evolve to meet the needs of its members. It may be hoped that if the debate continues room will be found for constructive suggestions. Some are made in the memorandum of the Winchester Division and will, no doubt, be considered when the holiday season is over and the newly elected Council of the Association begins its year of work.

## "MUSHROOM" POISONING

About two hundred varieties of edible fungi grow in England, but most of us would not risk eating any except the usual variety. The term "mushroom" is often used to cover all varieties of edible fungi, but it is preferable to limit it to the field or cultivated mushroom (*Psalliota campestris*). Though many edible fungi are peculiarly shaped and coloured, the most deadly of the poisonous ones, *Amanita phalloides* or the Death Cap, is easily mistaken for a mushroom. It grows mostly in woods, however, where mushrooms are rare, and its gills are permanently white, whereas those of the mushroom never are. The popular tests of edibility are all fallacious, and safety lies in being able to recognize the Death Cap on sight (chiefly by its white gills) or in making sure that only undoubted mushrooms are eaten. The Death Cap must be avoided at all costs, because poisoning by it is usually fatal. Krause<sup>1</sup> reported 7 deaths in 8 cases, and several similarly dismal series have been described.

The two cases of Death Cap poisoning described elsewhere in this issue by Dr D Lewes illustrate several characteristic features, including the fact that prolonged cooking does not destroy *Amanita* toxin. Both patients recovered without specific treatment, possibly because the poisonous fungi were well diluted with edible ones. Certain other fungi such as *Amanita muscaria* and *Inocybe fastigiata* contain muscarine, which causes blurred vision, sweating, and giddiness soon after ingestion. Three such cases were described in this journal last year by Wilson.<sup>2</sup> Mild effects resemble alcoholic intoxication, and certain Siberian tribes eat fungi for this reason.

From the point of view of treatment, cases of "mushroom" poisoning fall into two groups according to whether the symptoms are immediate or delayed. Those with early symptoms should be given atropine by injection and magnesium trisilicate or charcoal by mouth after gastric lavage. A delay of 8 to 12 hours in the onset of symptoms is characteristic of Death Cap poisoning, and this in itself, as urged by Birch,<sup>3</sup> justifies prompt specific treatment. In addition to gastric lavage and measures to prevent failure of liver function anti-phallic serum should be used if obtainable in time (a limited supply is kept at the Central Public Health Laboratory, London, NW9, Tel No Colindale 6041). Meusel and Orzechowski<sup>4</sup> recommend the use of choline chloride by intravenous drip and report two recoveries on this treatment.

The rabbit stomach-brain treatment of Limousin and Petit<sup>5</sup> must be mentioned because it was based on experimental observations and has been used with success. Unlike cats, rabbits do not die after eating the Death Cap, but the juice of the fungus is fatal if injected into rabbits, suggesting that the rabbit's stomach can destroy the toxin. Cats fed on *Amanita phalloides* mixed with rabbit's stomach survive several days, and if rabbit's brain is added they recover completely. However impracticable this treatment may seem in a very ill patient, the desperate nature of the emergency merits its consideration. The procedure is to give five uncooked minced rabbits' brains and stomachs daily for several days, but the treatment will be useless if started late. Melendro<sup>6</sup> found it impracticable. Eight of his nine patients died—the survivor being a woman five months pregnant.

Proof that *Amanita phalloides* is the cause of symptoms should be sought by inspecting any fungi left over from the meal and by having the vomit or stomach washings examined

<sup>7</sup> *Rev clin esp*, 1945, 17, 211.

seriously after the first month, and perhaps disappears altogether after 2 or 3 months. Pyle,<sup>7</sup> in the most accurate quantitative study yet made, showed that during treatment bacilli of widely varying degrees of resistance can be obtained from the sputum at any given stage and that a steady shift towards higher degrees of resistance proceeds. After 2 months organisms originally sensitive to about 1  $\mu$ g may withstand 100  $\mu$ g per ml, and, after 3, as high a concentration as 1,000  $\mu$ g per ml. This change was observed in 5 out of 8 patients studied. Sąduski and Swift<sup>8</sup> report similar findings. Their observations extended to 4 months, and at that stage all strains that could still be isolated showed increased resistance in varying degrees. Whether to continue a policy of long courses of treatment in view of such findings is a matter for serious consideration.

Perhaps the greatest unsatisfied popular demand for streptomycin is for pulmonary tuberculosis. The profession can do much to allay anxiety and even indignation about non-availability of the drug for the average patient by acquainting the public with the fact that for the great majority it would be of little benefit. Recent reports from the U.S.A., such as Muschenheim's,<sup>9</sup> confirm earlier findings that chronic lesions with fibrosis and cavitation respond comparatively poorly, though chemotherapy may help by making thoracoplasty practicable when previously it was not. Apart from cases of miliary tuberculosis, streptomycin is chiefly indicated for early acute exudative lesions, laryngeal and tracheo-bronchial ulceration also respond favourably.

Another and even larger field for the use of streptomycin is in the treatment of infections of almost all kinds due to many species of Gram-negative bacilli. Most of these are highly resistant to penicillin and almost all are sensitive to streptomycin *in vitro*. It does not follow that the infections caused by them will respond to treatment, typhoid fever illustrates this, and undulant fever can be arrested only if full doses of sulphadiazine are given in addition.<sup>10</sup> Bacillary dysentery has been successfully treated, so also, according to Pulaski and S. F. Seeley<sup>11</sup> and Leisti<sup>12</sup> has acute gastro-enteritis of unknown aetiology in infants. This may be an important use, for the drug can be given by mouth for such conditions, being neither destroyed in nor absorbed from the alimentary tract. Streptomycin is indicated in tularaemia and plague, also in meningitis due to any Gram-negative bacillus, notably *H. influenzae*, any Gram-negative bacillus septicaemia, and Friedlander's bacillus pneumonia. Large quantities of the drug have been used in the U.S.A. for treating urinary tract infections, with a fairly constant proportion—50% or more—of complete successes. The causes of failure are not perfectly understood, but they include obstructive lesions and probably incomplete alkalization of the urine before treatment. Whatever the cause of failure, it is accompanied by the acquisition of a high degree of resistance by the infecting organism, and second courses are therefore fruitless. Some bacteria not only become completely resistant to streptomycin but actually dependent on it for growth. This was first shown with meningococci by Miller and Bohnhoff,<sup>13</sup> as noted in these columns some months ago. The same extraordinary change has now been observed by Rake<sup>14</sup> in *Bact. coli*, and by Paine and Finland<sup>15</sup> not only in *Bact. coli* but in *Staph. aureus*,

*Ps. pyocyanea*, and *Proteus morganii*. These authors conclude on evidence based on this change that streptomycin probably acts as a metabolite antagonist. Whatever its precise significance, this sort of behaviour bodes ill for the ultimate future of streptomycin treatment. Acquired resistance is a permanent character, and it may not be long before such strains, derived from a case in which treatment failed, begin to be found in previously untreated patients.

## B.M.A. CRITICIZED

When such a vast scheme of reform as the National Health Service Act is introduced the transition from the old to the new is unlikely to be smooth. For six years the British Medical Association, through its Council and Representative Body, argued the case for the medical profession with three successive Ministers of Health, and during this period was subjected to criticism, some of it constructive and much of it destructive, for the way it conducted its business. It has been a difficult task for a voluntary organization to represent the interests of more than 50,000 medical men and women who by the nature of their work are self-reliant individualists. The onlooker who thinks he sees most of the game is at times tempted to think he can play it better than some of those trained to do so. No organization would claim to be perfect or free from the human capacity to err. But so long as it has put its hand to its task in good faith and with courage it can withstand the criticisms levelled at it. The correspondence columns of this *Journal* provide an open forum for medical men and women to discuss freely medical and professional problems, and to be outspoken in their criticism of medical institutions and persons in responsible positions. The catharsis of open criticism has its benefits.

In our correspondence columns this week Dr W. A. Bourne once more shows himself to be a somewhat severe critic of the Association to which he belongs, and in particular blames it for having concentrated on general principles to the neglect of the details of terms and conditions of service. But what would have been the position if the B.M.A. had entered into detailed discussions on the terms and conditions of service before the major controversies had been settled? There was, indeed, wide spread anxiety in the profession lest the B.M.A. should, by negotiating on terms and conditions of service, thereby unwittingly prejudice the issue of whether or not to enter the Service. Many were ready, for example, to criticize the B.M.A. for discussing the question and amount of compensation in relation to the prohibition in the Act of the sale and purchase of practices. In the face of a great deal of opposition among its members, the B.M.A. nevertheless had the wisdom to do this, and also, through the Spens Committee, to discuss in some detail the remuneration of general practitioners. The recommendations of the Spens Committee were accepted by the Government and welcomed by the majority of general practitioners. There would seem, therefore, to be little that is substantial in Dr Bourne's criticism beyond the sincerity with which he sustains it. And when he deplores the present situation "in which

## INTERNATIONAL CONGRESS ON MENTAL HEALTH

### GREAT ASSEMBLIES IN LONDON

An International Congress on Mental Health, attended by 2,000 delegates from more than fifty countries, was held at the Central Hall, Westminster, from Aug 11 to 21. The sessions on the first four mornings were under the auspices of the International Committee on Child Psychiatry, and on the first four afternoons under those of the International Federation for Medical Psychotherapy. During the second week the arrangements were made by the International Committee for Mental Hygiene, and the discussions then took a wider and less technical field.

The President of the Congress, Dr J R Rees, opened it with a speech of welcome and read a number of messages, including one from the World Health Organization and another from Mrs Eleanor Roosevelt. The Congress was under the patronage of the Prime Minister and Mr Eden, and its officers and committees included almost everyone prominently associated with psychiatry and psychology and mental health in this country.

In the second week of the Congress, in addition to the plenary sessions, over twenty organizations held specialist meetings. Speeches were in English and French, English speeches being simultaneously heard in French by means of an arrangement of earphones, and French speeches interpreted into English subsequent to delivery. The arrangements for the Congress, which have necessitated more than a year's hard work, reflected the greatest credit upon the organizing committee under the chairmanship of Dr Rees, the Congress organizer, Mr Michael Harvard, and the chief administrative officer, Miss Judith Jackson. Social events in connexion with the Congress included a Government reception, and receptions given by the Royal Society of Medicine, the British Medical Association, and the London County Council.

#### First Day

##### AGGRESSION IN RELATION TO EMOTIONAL DEVELOPMENT

The first session was devoted to the subject of aggression, which was introduced by Dr FREDERICK ALLEN (Philadelphia). He concentrated on the positive aspects of aggression—the 'going out' quality, as he called it. Aggression, he said, had become a sinister word, and with adequate justification, both in individual and in group behaviour. But it was necessary to restore to the concept of aggression the value of the 'going out' quality in all individuals—and nations for that matter—as a condition of creative and responsible action. "We want more of our children to develop the capacity to 'aggress and find their place,' not just as faithful precipitates of social forces, but as creators of the quality needed to sustain the virility of the race."

Dr NELLY TIBOUT, director of the Child Guidance Clinic, Amsterdam, described experiences with Dutch children during and since the occupation. One of the few clinical pictures practically unobserved before the war was of children who presented an almost complete loss of connexion with reality, while in a clownish way making superficial contacts in an attempt at recovery. Tremendous fears of being able to destroy and of being destroyed played a part in the mental life of very young children. The alarming fact had to be faced that many children in different countries had been placed in a situation which caused them to live on the borderland not only of physical but of psychical starvation.

Miss ANNA FREUD, who was received with special acclamation, described the Freudian theory of aggression in which the aggressive urges were considered to be the representatives of one of the two fundamental instinctive forces—that is, of the destructive instinct or death instinct. Their counterparts were the sex urges as representatives of the life instinct. Normally the development of aggression was intimately bound up with the developmental phases of infantile sexuality. Without this admixture of aggression none of the sex impulses could ever reach their aim. On the other hand, through this constant fusion with erotic impulses the aggressive urges were deprived of their destructive qualities and utilized for the purposes of life.

The general discussion which followed was scrappy owing to the severe time limit which had to be imposed on speakers. Dr JOACHIM FLESCHER (Italy) said that the fact was usually overlooked that the aggressive instinct, though primary, hid as a rule in the form of an alloy with its counterpart, the erotic instinct. Under the impact of frustration, especially in the auto-erotic stage, there was not only danger of aggression but of what he called "pathological progression." Dr MELANIE KLEIN said that during the first three or four months of life destructive impulses, persecutory anxiety, and splitting processes were at their height. In states of anger and hatred, aggression and persecutory anxiety reinforced each other. In normal development at about 4 to 6 months of age, when love and hatred—libido and aggression—towards the mother came closer in the infant's mind, his anxiety lest she be destroyed as an internal and external object by his sadistic impulses and fantasies led to depressive feelings, a sense of guilt, and the urge to make reparation. If such anxieties in early infancy were excessive in relation to the capacity of the ego to deal step by step with them, the result might be the pathological development of the child.

After contributions from Polish, Greek, and other delegates, the discussion was summed up by Dr EMANUEL MILLER (Maudsley Hospital), who referred to the growth of the aggressive process as both offensive and defensive. It represented a quasi-attack upon environment but also the creation of a defensive ambience, very much as certain powers surrounded themselves with buffer States. In inquiring into the life history of the child it was his habit always to include not only the genetic factor in the family but also intrauterine activity during the last period of gestation. He found that children active in the uterus during the last few weeks of gestation tended to be the active, forthcoming, and aggressive children.

##### GENESIS OF GUILT

This subject at the second session was opened in three papers, by Dr VAN DER WALLS (Amsterdam), who expounded the psycho-analytical theory of guilt, Dr A HESNARD (Toulon), who spoke as a psychiatrist, and the Rev T GILBY (Cambridge), who presented the religious viewpoint. "Probably," said Mr Gilby, "the maddest people are not seen by the medical psychologist, just as the most vicious people are not seen by the priest." The discussion was continued by delegates from Copenhagen and Harvard and by two French psychiatrists.

Dr ERNEST JONES, who presided, summed up the discussion by saying that it was a fundamental question, both philosophical and sociological, whether the sense of guilt was primarily inborn or acquired. The religious view was that it was inborn, and the Christian view that it dated from the fall of man. The decision on the question whether it was innate or not would determine whether a sense of guilt was normal or not. One view was that the individual began with a norm or conscience and experienced morbid deviations from it. Freud put forward the view that guilt proceeded from parental condemnation and punishment, this, being absorbed into the individual, produced a sense of guilt. The sense of guilt did not develop along a straight line, it interacted with other emotional attitudes. Fear, for example, might lead to a sense of guilt, and guilt equally to a sense of fear. "Conscience doth make cowards of us all." Similarly hate could generate guilt, and guilt could generate hate. Thus there were a series of vicious cycles which obscured the tracing of the simple instinct. The complexity of this problem called for much further investigation.

#### Second Day

##### THE FAMILY BATTLE-GROUND

Another aspect of aggression, this time in relation to family life, was discussed on the morning of Aug 12. The chair was taken by Dr GEORGE HEUYER (Paris), who said that the definition of aggression was still awaited, but whatever the definition one essential element was the tendency of the subject to attack antagonistic individuals or groups. The most important aspect of the matter was the relation of the child to other members of the family.

Professor VITOR FONTES (Lisbon) spoke of the forms of aggression before and after puberty. At puberty the psycho-

for the characteristic spores. Because a meal of "mushrooms" may contain more than one type of poisonous fungus it would be wise to do this even in cases with early symptoms because of the possibility of the late onset of Death Cap poisoning.

### SKIN SENSITIVITY TO STREPTOMYCIN

A number of side effects have been reported from the use of streptomycin parenterally, including fever, headaches, pain at the site of injection, vestibular and eighth nerve injury, joint pains, and drug rashes. Pulaski and de Baey<sup>1</sup> found that drug rashes occurred in 5% of their cases, they included urticarial, erythematous, maculo-papular, and haemorrhagic rashes. It would seem that antibiotics derived from fungi like penicillin and streptomycin are particularly apt to give rise to eczematous rashes from external contact. Strauss and Warring<sup>2</sup> reported a series of six cases occurring in twelve nurses administering streptomycin and rinsing out syringes. Patch-test investigation confirmed the diagnosis. Recently Crofton and Foreman<sup>3</sup> described a similar occurrence, and Dr C Stringfellow reports a further case in this issue of the *Journal* (p 387). The wearing of rubber gloves and avoidance of direct contact are suggested as precautionary measures.

### THE DANGERS OF TAR

Tar and its derivatives have long been notorious as a cause of skin diseases in those who work with these substances. Even the fathers of industrial medicine were aware of the malignant sores which attacked men who worked in pitch. Tar also has the sinister property of being the source of the anthracene oils—the principal high-temperature constituents—which are the only definite chemical compounds isolated up to the present time known to be actively carcinogenic. Of these the best known is benzopyrene 3, 4, which is present in coal tar to the extent of 0.003%. Others which can be derived from anthracene but which perhaps are not actually present in tar are dienzanthracene and methylcholanthrene. Among the great numbers of men employed in handling tar and its derivatives fortunately only a very small percentage develop cancer of the skin, though a great many more suffer from milder conditions, some of which can be considered precancerous. These have been the subject of study by many writers, and the latest among these is Dr Philip Ross, whose interesting paper appears elsewhere in this issue (p 369). He finds that tar workers are prone to develop a rather peculiar erythema which is brought on by sunlight or strong winds. Other conditions are acne, tar melanosis, and also a characteristic change in the skin which was christened by Prosser White "shagreen" skin and is marked by keratosis, pigmentation, and telangiectasis, with superficial fissuring and the possible development of papillomata. It seems to take about ten years of working in tar before shagreen skin develops, and there are very few subjective symptoms. Curiously enough, workers in tar seldom contract allergic eczematous dermatitis, the type of "dermatitis due to dust or liquids" so familiar to those who until the "appointed day" assisted in the administration of the Workmen's Compensation Act of 1925. This is the more remarkable as many derivatives of tar are well known for their harmful effects on the skin.

The new growths which may be caused by exposure to tar range from simple keratoses through papillomata of various kinds (which, however, should all be distrusted as precancerous) to epitheliomata. Great variations are

reported in the length of time required to produce the latter in tar workers. Ross states that it may be anything from 18 months to 34 years. He discredits, however, the dramatic case first reported by Bang of an epithelioma which resulted from a single splash of tar, a case which made so much impression that it has since been quoted repeatedly. The cessation of handling of carcinogenic substances by no means insures immunity, since growths have appeared after a latent period of many years. Fortunately tar epithelioma is a growth of low malignancy, and Ross recommends the employment of the contact low-voltage x-ray apparatus as the treatment of choice.

Since tar cancer was first made notifiable in 1920 there has been a steady increase in the yearly notifications. It is, however, probable that this increase is more apparent than real and is due to the increasing vigilance and interest of officials and medical officers. Prophylaxis is of course most important, and Ross suggests that this problem should be tackled from several directions. So far as possible all processes involving tar and pitch should be mechanized, and actual handling should be avoided wherever possible. Fumes and dust should be removed through efficient exhausts. Protective clothing of stout material should be provided, and workers should be trained to work as cleanly as possible and to change their underclothing daily, or as often as the coupon situation permits. Above all the use of "any old suit," thoroughly impregnated with tarry residue, is to be avoided. On the more positive side the employment of barrier creams is a distinct help—Ross mentions that Professor Kennaway has found that the use of a protective cream on the skin of a mouse considerably delayed the appearance of experimental tar growths. Although many more cases have been notified of late years the number of deaths from tar epithelioma has diminished.

### VOLUNTARY ACCELERATION OF THE HEART

Emotional individuals often have a persistently rapid pulse. Sometimes the tachycardia may reach 140 per minute, and such cases present obscure problems similar to those of effort syndrome. It is difficult to imagine how processes in the cerebral cortex bring about such a puzzling state of affairs. There are, however, normal healthy people who can accelerate the heart at will. In most of the recorded cases the possessors of the attribute have been medical students or physicians, and it is quite possible that this exceptional type of response may be much commoner than is generally imagined. Feil<sup>1</sup> and his colleagues have recently reported the case of a medical student who first observed his ability to accelerate his heart while recollecting a terrifying nightmare. During the period of acceleration he developed paraesthesiae in the hands and feet, tinnitus, and palpitation. He could stop the acceleration at will, whereupon the symptoms disappeared and he was left only with a feeling of fatigue. Quite apart from this ability, however, he knew that he was liable to attacks of tachycardia which he could not control voluntarily. When an electrocardiogram was taken it was found that he also had the Wolff-Parkinson-White syndrome of short PR interval and a bundle-branch-block type of ventricular complex. When he was given atropine he was able at first to accelerate his heart beyond the intermediate rise produced by the drug, but with full doses no further acceleration was possible. This study shows that a relationship exists between cerebral activity and the autonomic control of the heart rate. The voluntary acceleration of the heart in the individual concerned may have been made easier by his liability to attacks of tachycardia as part of the Wolff-Parkinson-White syndrome.

sical factor that led mostly to aggressive reaction was lity, which at this stage of development was strongly It was thus that in the transferred forms of aggression there appeared occasionally sexual perversions with a ore or less apparent sadistic content The family, in spite of certain inconveniences, was the best organization for the educative education of the child

Dr TORSTEN RAMER (Stockholm) said that the most important prophylactic measure against aggression was a psychological understanding by the parent of the individuality of the child and his reactions Each child should be handled according to his peculiarities and his stage of development Not only parent but pre-parent education was important Certain social measures were also to be recommended The work of mothers outside the home should be limited, at all events it should be no more than half-time Cramped housing favoured the occurrence of aggression in the family, as also, according to Stockholm experience, did the crowding of large families into blocks of dwellings in the same area Collective child welfare also led to an increase of aggressiveness if the groups were too large

Professor D R MACCALMAN (Aberdeen) agreed in magnifying the home, which made possible an adjustment therapy for the child Aggressive tendencies could best be transmuted against a background of stable affection If aggression was not thus absorbed and controlled in early life, any later attempt would prove difficult and costly His own experience had convinced him that the early stages of development would be less productive of aggression if a determined attempt were made to give parents some knowledge and understanding of the fundamental needs of young children As matters stood, parents took this fundamentally important task without guidance Even the worst of bad parents met with in a child-guidance clinic responded to careful influence "There is much evidence to show that the bad parent is better than none at all" In a wider application of the subject Professor MacCalman quoted a Chinese proverb 'If there is righteousness in the heart there will be beauty in the character, if beauty in the character, harmony in the home, if harmony in the home, order in the nation, if order in the nation, peace in the world'

The general discussion was opened by Dr RENE DE MONCHY (Sweden), who said that the existence of aggression in family life should not be regarded as an unfortunate occurrence but as a necessity It was usual to associate the word with the externalized form of aggression, but the aggression directed inwards was of equal importance Sometimes it took the form of masochism, but that was only the extreme and pathological form of a normal and necessary impulse He instanced the manner in which parents repeated in their attitude to their children their own childish experience A young mother, when asked by her hostess whether her little son would like some cake, replied immediately, "Don't give him anything," and afterwards realized that she was literally repeating what her own mother used to say when out visiting, and how much she had resented it Professor F K GOKAY (Istanbul) gave an account of social work in Turkey, where they are investigating the effect of gangster films in manufacturing adolescent criminals, and also where they have prohibited accounts of suicide in the press Dr L CHENG (China) said that psychiatry was very new in China, and there were few psychiatrists in that country Family relationships had helped to maintain stability in Chinese society for generations, but under the impact of western civilization standards were breaking down However, there were very few cases of senile psychosis in China, thanks to the fact that old people did not worry about what was to become of them, knowing that their children would look after them

The discussion was continued by Dr KATE FRIEDLANDER (London), Dr KAREN SIMONSEN (Denmark), and Dr ERNST KRIS (New York), who warned against too sharp a division as between the loving and the rejecting mother Even the most loving mother was not loving to the same extent at all times, and not all the needs of the child would find in her equal facilities for fulfilment Professor MACCALMAN, taking up the contribution of Dr Cheng, said that chess originated in China and seemed to him an excellent sublimation of aggression in war Indeed, it was traditional in this country that sport canalized aggressiveness, and the time might come when the

playing fields of Eton would be significant of a greater achievement than the winning of the battle of Waterloo

#### DYNAMICS OF PSYCHOLOGICAL DISORDER

At the afternoon session, under the chairmanship of Professor H FULCHIGNONI (Rome), the Congress returned to the subject of guilt, and, as on the previous day, the religious and the psycho-analytical conceptions were contrasted Professor D BRINKMANN (Zurich) read a highly philosophical discourse on the subject, and he was followed by Dr JOHN RICKMAN (president of the British Psycho-analytical Society) with a paper emphasizing the depressive aspects of guilt Dr Rickman said that guilt could not be considered in isolation It was one kind of psychical action in a complicated, interconnected set of psychical actions which appeared to serve the purpose of keeping the organism in a quasi stable equilibrium He listed a number of reactions to guilt, such as the drive to restitution, the compulsive urge to propitiation of an aggressor, and an undue amount of social conformity, compulsive behaviour, and so on, and the wide range of cases of sexual anomaly in which the sexual act was felt to be an injury to the partner or at least a degradation (leading to impotence or frigidity or to a Don Juan-like compulsive change of lover) He also added, though only on the borderline of the present subject, that a reaction to guilt might take the form of an interest in religious and charitable organizations In the child, said Dr Rickman, guilt began early, and so did the considerable cultural restraint of its aggressive and other asocial impulses Certainly by the time the child was 4 years of age it was a cultural unit, though not yet a stable one "A child needs very little teaching about what is right and wrong, it is greatly helped if it is left to find its own way to a good relation even to not-so-good parents A parent's failure to recognize the child's capacity for guilt is a failure to recognize that it is a human being"

The chair for the general discussion was taken by Dr H CRICHTON-MILLER, who spoke of the relevance of this subject to world peace The behaviour of racial and national groups depended upon the values which were accepted by their leaders There was a time when civilization stood for integrity in social and personal relationships, or at least that situation was being approached Now the human race was facing starvation and possible destruction largely because leadership had fallen into the hands of men who put self-interest and expediency before integrity How far could mental health in the individual citizen secure integrity of leadership? How far could truth and honesty be reinstated by the improved mental health of the citizen? Certainly to some extent, but equally certainly not in full measure, and there must be an external norm to which personal and communal values were to be related Psycho-analysis had taught them that the old parental values, passing down by heredity, identification, and fixation, led to serious impairment of spiritual freedom, and, as they were all agreed, it was on spiritual freedom that democracy was based

Dr VAN DER HOOP (Amsterdam) opened the discussion, and was followed by Dr CLIFFORD SCOTT (London) who said that his experience was that even in the most ill patients there had been moments of pre-ambivalent love just as there had been moments of pre-ambivalent hate, and that there was much capacity for love even in the most guilty Other speakers were Dr WALTER FURSTENHEIM (Great Britain), Mrs MELANIE KLEIN (Great Britain), Dr J FLESCHER (Italy), and Dr DEBROWSKI (Poland) Dr W C HULSE (United States) pointed out what he considered to be a significant difference between the American and German soldier who broke down under the impact of war The American soldier asked, in a large majority of cases, "What have I done in this conflict that I ought not to have done? I have killed a man, or I have given orders to others whereby men have been killed" There were an enormous number of neurotic disturbances of that kind On the other hand, the German soldier in a similar situation did not feel guilt of that kind, but he would ask, "What have I not done that my superior asked me to do?" He was occupied continually with his relation to his superior officer, the father figure, whereas the American soldier in his psychological breakdown revealed a quite different guilt pattern Much more attention should be paid to the cultural factor which played an important part in the mobilization of feelings of guilt

### Rutin in Capillary fragility

Rutin is a crystalline glycoside obtained from the leaves and flowers of buckwheat. Recent reports attribute to Rutin the property of reducing capillary fragility when this is abnormally raised.

In our research laboratories a limited quantity has been isolated from buckwheat grown in this country and is available in the form of tablets.

Rutin A & H is suggested for administration in haemorrhagic conditions due to increased capillary fragility or permeability, especially when this condition is associated with hypertension, nutritional deficiency or toxic effects of drugs.

Literature and price on application.

social factor that led mostly to aggressive reaction was quality, which at this stage of development was strongly

It was thus that in the transferred forms of aggression there appeared occasionally sexual perversions with a more or less apparent sadistic content. The family, in spite of certain inconveniences, was the best organization for the affective education of the child.

Dr TORSTEN RAMER (Stockholm) said that the most important prophylactic measure against aggression was a psychological understanding by the parent of the individuality of the child and his reactions. Each child should be handled according to his peculiarities and his stage of development. Not only parent but pre-parent education was important. Certain social measures were also to be recommended. The work of mothers outside the home should be limited, at all events it should be no more than half-time. Cramped housing favoured the occurrence of aggression in the family, as also, according to Stockholm experience, did the crowding of large families into blocks of dwellings in the same area. Collective child welfare also led to an increase of aggressiveness if the groups were too large.

Professor D. R. MACCALMAN (Aberdeen) agreed in magnifying the home, which made possible an adjustment therapy for the child. Aggressive tendencies could best be transmuted against a background of stable affection. If aggression was not thus absorbed and controlled in early life, any later attempt would prove difficult and costly. His own experience had convinced him that the early stages of development would be less productive of aggression if a determined attempt were made to give parents some knowledge and understanding of the fundamental needs of young children. As matters stood, parents took this fundamentally important task without guidance. Even the worst of bad parents met with in a child-guidance clinic responded to careful influence. "There is much evidence to show that the bad parent is better than none at all." In a wider application of the subject Professor MacCalman quoted a Chinese proverb: "If there is righteousness in the heart there will be beauty in the character, if beauty in the character, harmony in the home, if harmony in the home, order in the nation, if order in the nation, peace in the world."

The general discussion was opened by Dr RENE DE MONCHY (Sweden), who said that the existence of aggression in family life should not be regarded as an unfortunate occurrence but as a necessity. It was usual to associate the word with the externalized form of aggression, but the aggression directed inwards was of equal importance. Sometimes it took the form of masochism, but that was only the extreme and pathological form of a normal and necessary impulse. He instanced the manner in which parents repeated in their attitude to their children their own childish experience. A young mother, when asked by her hostess whether her little son would like some cake, replied immediately, "Don't give him anything," and afterwards realized that she was literally repeating what her own mother used to say when out visiting, and how much she had resented it. Professor F. K. GOKAY (Istanbul) gave an account of social work in Turkey, where they are investigating the effect of gangster films in manufacturing adolescent criminals, and also where they have prohibited accounts of suicide in the press. Dr L. CHENG (China) said that psychiatry was very new in China, and there were few psychiatrists in that country. Family relationships had helped to maintain stability in Chinese society for generations, but under the impact of western civilization standards were breaking down. However, there were very few cases of senile psychosis in China, thanks to the fact that old people did not worry about what was to become of them, knowing that their children would look after them.

The discussion was continued by Dr KATE FRIEDLANDER (London), Dr KAREN SIMONSEN (Denmark), and Dr ERNST KRIS (New York), who warned against too sharp a division as between the loving and the rejecting mother. Even the most loving mother was not loving to the same extent at all times, and not all the needs of the child would find in her equal facilities for fulfilment. Professor MACCALMAN, taking up the contribution of Dr Ch'eng, said that chess originated in China and seemed to him an excellent sublimation of aggression in war. Indeed, it was traditional in this country that sport canalized aggressiveness, and the time might come when the

playing fields of Eton would be significant of a greater achievement than the winning of the battle of Waterloo.

#### DYNAMICS OF PSYCHOLOGICAL DISORDER

At the afternoon session, under the chairmanship of Professor H. FULCHIGNONI (Rome), the Congress returned to the subject of guilt, and, as on the previous day, the religious and the psycho-analytical conceptions were contrasted. Professor D. BRINKMANN (Zurich) read a highly philosophical discourse on the subject, and he was followed by Dr JOHN RICKMAN (president of the British Psycho-analytical Society) with a paper emphasizing the depressive aspects of guilt. Dr Rickman said that guilt could not be considered in isolation. It was one kind of psychical action in a complicated, interconnected set of psychical actions which appeared to serve the purpose of keeping the organism in a quasi-stable equilibrium. He listed a number of reactions to guilt, such as the drive to restitution, the compulsive urge to propitiation of an aggressor, and an undue amount of social conformity, compulsive behaviour, and so on, and the wide range of cases of sexual anomaly in which the sexual act was felt to be an injury to the partner or at least a degradation (leading to impotence or frigidity or to a Don Juan-like compulsive change of lover). He also added, though only on the borderline of the present subject, that a reaction to guilt might take the form of an interest in religious and charitable organizations. In the child, said Dr Rickman, guilt began early, and so did the considerable cultural restraint of its aggressive and other asocial impulses. Certainly by the time the child was 4 years of age it was a cultural unit, though not yet a stable one. "A child needs very little teaching about what is right and wrong, it is greatly helped if it is left to find its own way to a good relation even to not-so good parents. A parent's failure to recognize the child's capacity for guilt is a failure to recognize that it is a human being."

The chair for the general discussion was taken by Dr H. CRICHTON-MILLER, who spoke of the relevance of this subject to world peace. The behaviour of racial and national groups depended upon the values which were accepted by their leaders. There was a time when civilization stood for integrity in social and personal relationships, or at least that situation was being approached. Now the human race was facing starvation and possible destruction largely because leadership had fallen into the hands of men who put self-interest and expediency before integrity. How far could mental health in the individual citizen secure integrity of leadership? How far could truth and honesty be reinstated by the improved mental health of the citizen? Certainly to some extent, but equally certainly not in full measure, and there must be an external norm to which personal and communal values were to be related. Psycho-analysis had taught them that the old parental values, passing down by heredity, identification, and fixation, led to serious impairment of spiritual freedom, and, as they were all agreed, it was on spiritual freedom that democracy was based.

Dr VAN DER HOOP (Amsterdam) opened the discussion, and was followed by Dr CLIFFORD SCOTT (London), who said that his experience was that even in the most ill patients there had been moments of pre-ambivalent love just as there had been moments of pre-ambivalent hate, and that there was much capacity for love even in the most guilty. Other speakers were Dr WALTER FURSTENHEIM (Great Britain), Mrs MELANIE KLEIN (Great Britain), Dr J. FLESCHER (Italy), and Dr DEBROWSKI (Poland). Dr W. C. HULSE (United States) pointed out what he considered to be a significant difference between the American and German soldier who broke down under the impact of war. The American soldier asked, in a large majority of cases, "What have I done in this conflict that I ought not to have done? I have killed a man, or I have given orders to others whereby men have been killed." There were an enormous number of neurotic disturbances of that kind. On the other hand, the German soldier in a similar situation did not feel guilt of that kind, but he would ask, "What have I not done that my superior asked me to do?" He was occupied continually with his relation to his superior officer, the father figure, whereas the American soldier in his psychological breakdown revealed a quite different guilt pattern. ### THE STRETCHING SCREW CALLIPER

Mr HORACE DAVIES, visiting orthopaedic surgeon, Birkenhead Municipal Hospital and Whiston County Hospital, writes: It is with some trepidation that I describe the following modification of the time-honoured walking calliper. Adjustment of calliper length to individual comfort and requirements by the conventional sliding bar and lock-screw principle is not a precision

method although mechanically very sound. The principle that I have applied for the adjustment of calliper length is that of the stretching screw commonly used for cable-tightening. From the diagram it will be seen that the calliper side-steels are divided and coupled about 10 in (25 cm) above the extension ends. The coupling is by means of a left- and right-hand

threaded tube which screws over corresponding left- and right-hand threads in the side-steels. To prevent rotation the end of the top steel is shaped into a thin flat projection which slides into a corresponding slot cut in the end of the lower steel. By turning the coupling with its milled centre adjustments can be made easily and with precision. The required position is then set by the lock nuts.

Continuing the series of reports summarizing the results of clinical surveys of the nutritional state of certain sections of the community, E W Adecock, H E Magee, E H M Milligan, and H S Townsend describe in a recent issue of the *Monthly Bulletin of the Ministry of Health* (1948, 7: 453) the results of investigations undertaken between February 1947, and May 1948. Representative samples of three groups were surveyed—adolescents, housewives with adolescent children and school-children. In none of the groups was any frank deficiency disease observed, and in the adolescents and school-children the nutritional state was well maintained as compared with past years. The assessment of the state of nutrition of housewives from the results of the examination of the 652 women who were to be medically examined proved difficult: 87.4% were considered to be of good 10.9% of fair, and 1.7% of poor nutritional status. In general it may be said that this group of mothers, with children aged from 12 years upwards appears to be the most vulnerable section of the population yet examined.

## Correspondence

### The B.M.A. Under Fire

SIR—When the B.M.A. Study Groups began, about six years ago, I was a member, and I well recall my astonishment that no discussion was allowed on terms of service. Since then, as general practitioner and consultant, I have argued with the Divisional Executive Committee of which I have been chairman, and which includes a member of Council, that clear conceptions of terms of service were essential to the B.M.A. and that without them no real hold on the body of the profession was possible. My arguments were futile, the official bodies of the Association stuck to general conceptions, the fundamental point at issue was made refusal to enter a whole-time salaried service, this was put to interminable meetings of the profession. It may be that the B.M.A. never imagined the granted this all necessary was won, and then the Minister agreed. He agreed, not to any proposal made direct to him by the B.M.A., but to a proposal made by the Royal College of Physicians, who put in their resolution no less than had been said by innumerable speakers at innumerable meetings of the profession. It may be that the B.M.A. never imagined the Minister would give an amending Act, and made that the cover for a demand for further amendments, it may be that they have not the essential ability to bring the enormous weight of opinion they undoubtedly accumulated to bear on the one man who mattered at the time that mattered on the issue that mattered—in other words, they lack a negotiator. At any rate, when the Minister gave way, the B.M.A. was left with no practical policy, it had never allowed itself to consider terms, and was left hopelessly in the air. A negotiator must know what he wants, or he cannot begin to serve his party. Hence the impotence of the B.M.A. and the sense of frustration of its members. Hence the deplorable present situation in which regulations are pouring out from overworked Civil Servants who know nothing of practical detail, instead of the situation we idealists had pictured in which the B.M.A. would have had plans ready in advance of the Ministry, instead of protests several weeks too late.

To any consultant who has watched all this the present situation is alarming. It should be pointed out that the B.M.A. Consultants and Specialists Body is nominally autonomous and its decisions are "not to be subject to approval of the Council or the Representative Body except in so far as they might affect other forms of practice or other aspects of the policy or activities of the Association." This is not autonomy at all. Every man who enters consulting work leaves general practice at some stage of his career, every pound that goes to consultants deprives the general practitioner or will do. Every rise in the standard of consultant or specialist practice will put a few general practitioner-consultants out of consulting practice. And every decision on these and similar fundamental matters the B.M.A. Consultant and Specialist Body makes will be liable to veto by the Council or Representative Body. Of course, the B.M.A. is not clear on the matter, at a recent regional meeting of the consultants a B.M.A. official told those present that the meaning of the Cambridge resolution was not clear to him but added, "We understand it at B.M.A. House." How can this serve any useful purpose? What confidence can be felt in such a statement? It is the old situation over again, leave things to the B.M.A., who know who negotiate, who have the machinery. The result seems likely to be the same unless the B.M.A. is very careful. The disillusion of the general practitioners will be equalled only by that of the consultants. And what clear conceptions of a consulting service has the B.M.A.? Can it claim to know more than the professors of universities and deans of medical schools? How many new representatives better than these experienced men is the B.M.A. prepared to produce? And where is it going to find them if not in the Colleges?

This letter is written by a member of the B.M.A. who has served it locally to the best of his ability, and who has seen many of his worst forebodings proved miserably true. It is an unfortunate thing that honest criticism is called disloyalty, when

is not regarded as an abstruse form of mental defect or emotional displacement. But one more effort seems called for, and has been made. Can the B M A not grant the consultants and specialists true autonomy—dominion status? And can they not recognize the vital part the Colleges must play, that academic and financial matters are no longer separable, and that for the good of all the leading consultants should be recognized as leaders?—I am, etc.,

W A BOURNE

### Paratyphoid Osteomyelitis

SIR—The two examples of paratyphoid B osteomyelitis reported by Drs Rachmiel Rozansky, E N Ehrenfeld, and Y Matoth (Aug 7, p 297) prompted me to read my notes of a similar probable, though bacteriologically unproved, case of this rare condition. Briefly, this was a girl of 16 admitted to Chase Farm Hospital in 1942 with pyrexia and pain in the lower back of one week's duration. Osteomyelitis of the spine was considered but investigation showed that she was suffering from paratyphoid B. No radiological signs were present while the pyrexia lasted. A tentative diagnosis of early ankylosing spondylitis was made, and she was put in a plaster bed for three months. X-ray examination then showed complete destruction of the body of the fifth lumbar vertebra. Further immobilization resulted in a stable and symptomless spine. She was followed up until 1945, and I saw her in the street last year apparently quite well.

The interval of 32 years between the enteric fever and bone abscess in Dr Rozansky's second case warns me that although bone destruction has occurred my patient may not be out of the wood yet.—I am, etc.,

London N 14

C ALLAN BIRCH

### Who Shall Minister to the Neuroses?

SIR,—Is it fully appreciated that Dr C A H Watts has rendered a great public service by his unassuming article on this subject (July 24, p 214)? For he demonstrates therein that sufferers from the anxiety state can be very helpfully treated psychologically on simple common sense lines by a general practitioner.

It is admitted that about a third of our chronic patients are solely in need of psychological treatment of a kind which the average doctor has neither the time nor the education to provide, and only a minority have the necessary flair. His ordinary fees do not reward the extra time involved, and he naturally dislikes to surrender his influence over his patient by invoking a psychological specialist who is needed for complicated cases. But most cases can be treated on simple lines as Dr Watts has shown.

I see no solution of this pressing problem until a considerable proportion of general practitioners have been trained to treat the body-mind—recognized by a later degree (perhaps an M D) and rewarded by higher fees. The M B only qualifies to treat the body. Ordinary examinations test knowledge rather than the ability to use it. Special methods would be needed to detect the flair needed in this treatment. To treat the body mind can scarcely be taught in lectures but can be learnt (in a few years) from patients with the help of books such as *The Common Neuroses* by T A Ross (1937).

I speak from experience. Many years ago I realized as a general physician that it was necessary to treat the body-mind on such simple common-sense lines as Dr Watts advocates. Complex cases were beyond my scope, but they were a minority. This deplorable hiatus in treatment must be filled. To produce enough general practitioners of the right type will need long-term planning on a national scale. Dr Watts has shown that it is possible.—I am, etc.,

Beverly Yorks

F C EVE

### Use and Abuse of Tonsillectomy

SIR—Mr T B Layton's reference (Aug 7, p 310) to the prohibition of tonsillectomy during the poliomyelitis epidemic last year brings up a very important matter—namely, the necessity or otherwise of such a step. As the prohibition was not absolute a good many surgeons must be in a position to

quote figures of cases done during the epidemic. I personally did nearly 500 cases without anyone developing the disease and conversation with colleagues leads me to believe that my experience was not exceptional.

Statistics from other countries point to an increased liability to poliomyelitis after recent operations on the upper respiratory tract. But is this increased susceptibility sufficiently great to warrant the prohibition of such operations? No doubt statistics, if such were available, would show an increased liability to all diseases involving the upper respiratory tract after recent operations on this region, so logically such operations should stop during practically all epidemics. This may well result in tonsil and adenoid operations ceasing for a large part of the year. If the contention that the number of such operations is excessive is correct, this may be a blessing in disguise. But is it correct?

In spite of discouragement from the Ministry of Education doctors and nurses continue to advocate, and parents to demand the operation in a large number of cases. Whether this number is excessive, or in other words includes an appreciable number of tonsils which are normal or likely to return to normal is a matter which cannot be decided without scientific research. I therefore heartily endorse Mr Layton's statement that the profession as a whole should reconsider its approach to tonsillectomy, and I think we would be justified in looking to the Medical Research Council for a lead in this matter of great practical importance.—I am, etc.,

Birmingham 15

ROBERT EVANS

SIR—I should like to support the views expressed by Mr T B Layton (Aug 7, p 310). Neglect of chronic nasal catarrhs causes, as in measles too, infection of the middle ear. Damage having been done removal of tonsils for their further treatment can do no good. One of the complications following tonsillectomy is middle-ear disease. Diastolization can cure most nasal catarrhs or, if taken early nasal oil may be successful. Sinusitis leading to enlarged adenoids can be relieved by Proetz's displacement method. Looking only at tonsils cannot decide the need for the removal of adenoids. I think the decision should be left to the parents and doctors should not dictate to them as to necessity. Dr J Alison Glover's survey of 90,000 tonsillectomies showed the rate of operation varied from 1% to 45% in different counties, and at one school the number increased with the income of the parents. Where the operation was reduced in number the so-called "dangers" of so-called "septic tonsils" did not exist. The consultant aurist at the Manchester health department has shown the value of treating nasal catarrhs and the reduction of tonsillectomies.—I am, etc.,

Blyth

A G NEWELL

SIR—I have read with great interest the letter (Aug 7 p 310) by my old friend Mr T B Layton on the use and abuse of tonsillectomy, and I congratulate him on an excellent and reasoned exposition of this subject, which is, especially to general practitioners a most interesting and often worrying problem.

As he so wisely says "We cannot conduct the art of medicine by administrative fiat." I am convinced that many tonsils and adenoids are removed unnecessarily and I have seen many bitter disappointments in parents at the unrealized though expected improvement in their children after this operation. The converse equally holds good, and I have seen many a child steadily regress in health owing to the parental refusal of an obviously necessary operation. Following a sore throat many tonsils are removed owing to mere enlargement, through the failure to realize that this hypertrophy is only physiological and temporary. In my opinion the two pointers for operation are (1) glandular enlargement plus the fact that pus is exuded from the tonsil on pressure, and (2) obstruction to the air intake most often but by no means always due to adenoid vegetations. The patient showing mouth breathing by night with consequent chest deformities.

Much has been written on symptomatology but my submission is that epidemic or no each case must be judged on its individual merits.—I am etc.

London SW 1

DESMOND MACMANUS

### Thyroidectomy Fatality Rate

SIR—In his comparison of safety between thiouracil and surgery for thyrotoxicosis, Professor H P Himsworth states (July 10, p 61) that "it is probable that the mortality rate (after surgery) in the best general hospitals, both in this country and abroad, is not far below 2%". I cannot help thinking that this is a most pessimistic estimate for modern thyroid surgery. For a period of 29 years I have had the honour to anaesthetize for three surgeons who specialized in thyroid work, and for the whole period the total operative mortality rate for thyroidectomy was 0.75%. This includes all patients who died in the hospital or nursing-home.

In recent years, however, owing to the advances in pre-operative treatment and in surgical and anaesthetic techniques the mortality rate has fallen to a very low figure there having been only two deaths in the last consecutive 1,000 cases (0.2%). There is no reason to suppose that this figure differs appreciably from that obtaining generally, and I would suggest that the insertion of a decimal point in Professor Himsworth's estimate would give a more accurate idea of the present day mortality rate from thyroid surgery. I should, perhaps, add that the majority of the thyroidectomies referred to were performed at St Bartholomew's Hospital either in London or at Hill End—I am, etc.,

St. Albans Herts

C LANGTON HEWER

### Prevention of Dust Diseases of the Lung

SIR—From this correspondence (July 17, p 172, and Aug 7 p 311) it would appear that so far we do not possess a face mask or respirator which in use will efficiently arrest dangerous dust particles and assure the workman of protection against pneumoconiosis. At the same time it seems agreed that face masks do not represent effective action directed to the control of the disease. From practical experience one thing is certain—namely, that no mask has yet been devised which heavy manual workers, particularly workers at the coal-face can comfortably wear throughout a day's work.

As a temporary expedient practical scientists are seeking to design a mask which is efficient in arresting the dust and at the same time is acceptable to the workman. To those scientists I would suggest they have a further responsibility which is to ensure that the wearing of the mask, its day-to-day storage, and disposal of pads do not bring new dangers. Workmen and employers are exceedingly careless in what to medical men are elementary matters of hygiene. It is a common observation at workplaces to see masks still fitted with soiled pads thrown into a common receptacle, from which masks are taken promiscuously when required, while soiled infected pads are discarded anywhere. The recent article by Dumbell, Lovelock and Lowbury (*Lancet*, July 31, p 183) on "Handkerchiefs in the Transfer of Respiratory Infection" may not be entirely irrelevant to this aspect of the problem, especially as it has frequently been argued in the literature that respiratory infection by pathogenic organisms may modify adversely the action of noxious dust in the lungs.

This is no place for a discussion of measures for the effective control of pneumoconiosis in coal-mines, but I would venture to ask your correspondents, Dr A Harper and Dr J M Morgan (Aug 7 p 311) or any others, what is the *earliest harmful evidence* in coal-miners at which the workman should be advised to give up his skilled occupation and seek alternative work? Or, in the language of the compensation schemes "What constitutes the disease to a *dangerous* degree?" This is the question which more than any other urgently demands a clear unequivocal answer now—I am, etc.

Glasgow

A MEIKLEJOHN

### Fibrositis

SIR—The article on fibrositis by Dr James Cyriax (July 31, p 251) certainly offers a simple solution to an aged and complex problem. The conclusion that he "forced on the unprejudiced observer" that "the symptoms of rheumatic fibrositis coming on for no apparent reason are the result of articular lesions" and "the underlying principle of treatment" that he wishes to teach the simple observer, that of the reduction of the intra-articular lesions by local manipulation are simple if not factual.

It would be interesting to know if Dr M Woodhouse is as happy about the finality of the conclusions drawn from his necessarily limited electromyographic studies as is Dr Cyriax.

It is an accepted fact that many people who in the past have been diagnosed as suffering from fibrositis and neuritis are really suffering from symptoms due to intra-articular lesions such as prolapsed and fragmented intervertebral disk in the cervical or lumbar regions and that the principle of local treatment is either movement or rest. Dr Cyriax has been among those who have impressed this fact on the medical profession. This, however, is not the problem of 'fibrositis,' and in consequence the solution offered in this article is no solution.

"Fibrositis" is a clinical term commonly used to describe the pain which seems to be located in the soft tissues of the limbs and for which there is no obvious cause. In practice the diagnosis is based on the exclusion of known systemic diseases or local disorders. Pain and stiffness are the cardinal symptoms occurring particularly on movement and localized on clinical examination to the subcutaneous tissues, superficial and deep fasciae, aponeurosis, ligaments and capsules of joints, tendons and tendon sheaths, bursae, periosteum and the sheaths of the nerve trunks.

It is true that we have no adequate evidence that fibrous tissue is affected primarily, but we do know many of us from personal experience that sitting in a draught may be followed by a stiff neck or lumbago, also we know that pain in the shoulder may disappear after the removal of a septic tooth. We do know that the industrial worker the harassed young housewife, and the plump, middle-aged ladies among our acquaintances frequently suffer from "fibrositis". Many of us know that the "reduction of an intra-articular lesion" has not only failed to relieve their symptoms but has made them worse.

"Fibrositis" is a problem in general medicine. At the present time "unprejudiced" and far from simple observers are studying this problem and I would bring to the notice of Dr Cyriax and his would-be disciples the many papers and books on this subject recently published in the English language. I would mention only those by Weddell, the anatomist; Draper the constitutionalist; May Wilson, the clinician and geneticist; Halliday, the industrial physician and psychiatrist; and Ling the sociologist. Hench, Stone, and other physicians whose primary interest is in rheumatism have also made valuable contributions. Finally I refer Dr Cyriax to the papers by Drs Bauwens, Harman, and Dukes of his own hospital.

The problem of "fibrositis" is complex. To solve it the biochemist, the geneticist, the pathologist, and the clinician will need to work together as a team probably for quite a long time to come—I am, etc.

London W 1

FRANCIS BACH

### Treatment of Chronic Varicose Ulcers

SIR—I read the paper by Messrs John Borrie and E Vernon Barling on chronic varicose ulcers treated by lumbar sympathectomy (July 24, p 203) with great interest. When I was Mr (now Professor) Ascroft's house-surgeon we had a patient suffering from thrombophlebitis obliterans with large ulcers in the region of his malleoli which caused him much pain. To relieve this pain Mr Ascroft divided the superficial nerves supplying the area in question, and to our surprise and gratification not only was the patient's pain relieved but the ulcers quickly became smaller and healed within a very short time. Mr Ascroft attributed this effect to the improved local circulation, as the sensory nerves also carry some of the sympathetic fibres to the area.

Since then I often divided or crushed the great saphenous nerve just below the knee when I did a Trendelenburg operation in patients with varicose ulcers over the medial malleolus and always had the impression that this simple manoeuvre speeded the healing of the ulcer as well as relieved the patient's pain immediately.

The nerve is easily found a couple of inches below the knee, where it lies close to the saphenous vein which I ligate in this place as well as in the thigh in these cases. Often the nerve is not in a single trunk but divided into several strands. In the case of ulcers in the region of the lateral malleolus the sural and the cutaneous branch of the superficial peroneal nerve require division. This little operation adds only a few

minutes to a routine Trendelenburg operation and is, in my opinion, always worth while doing before embarking on a major operation like lumbar sympathectomy—I am etc

Coventry

P E ROLAND

### Prevention of Venereal Disease

SIR—I feel obliged to add my testimony on the subject of prevention of venereal disease to that of your correspondents in the *Journal* of July 31 (p 268). I am sure that to rely upon methods of prophylaxis to be applied after exposure to infection is to court failure. The attention to detail necessary to make them efficient is rarely available, and the false sense of security given simply encourages risks to be taken. Dr Earle Moore, with his vast experience, has no doubt that prophylactic treatment if properly carried out can be of value, but he says the average man will not take the necessary trouble, and when one remembers how often the patient was more or less under the influence of alcohol when the risk was taken this is not surprising. If anything is to be done on such lines of prevention surely the use of a rubber sheath is much simpler and more likely to be carried out, this indeed is what I am in the habit of telling those patients who seem unlikely, in spite of all one can say to abstain from future risks.

Finally I must add that I am astonished Lord Horder (July 17 p 171) should take such a pessimistic view of the present situation. Looking back over the 25 years that I have been in charge of a fairly busy clinic I feel that, owing chiefly to the action of the Ministry of Health in making the public "V D conscious" and in providing free treatment, we can reasonably anticipate a continuation of the improvement which was so marked before the war and which is now showing itself again. That war conditions should cause a relapse was inevitable and to be expected. Has not this happened in every war since syphilis was first brought to Europe by soldiers in the sixteenth century?—I am, etc,

East Croydon Surrey

P W HAMOND

SIR,—The sexual requirements of the individual vary immensely, and each is entitled to judge for himself or herself whether extramarital relations are right or wrong. There can never be a standard sexual morality. The problem is therefore a moral one for the individual only. To regard V D as a moral problem, as does Dr G L Russell (July 31, p 268) is to be prejudiced. It would appear from what Miss K B Hardwick writes (p 269) that the Association for Moral and Social Hygiene, having found chastity as an ideal unsuccessful, is now preaching chastity as an anti-V D device.

The first essential in any campaign against V D is to stop looking upon extramarital relations as a disease in itself. The lack of a marriage certificate does not transform sexual experience from something beautiful into something ugly and shameful, but the present official outlook of Church and State, by driving sex into back streets and sordid lodgings, does precisely that, and at the same time favours the spread of V D. The inevitability of extramarital sex relations must be accepted, and every effort made to keep such relations, if not on a spiritual, at least on a healthy physical level.

All anti-V D appliances should be banned until some really efficient method is discovered, and V D propaganda stopped. Would not anti-T B propaganda be of more value in its own field? Surely the early symptoms of pulmonary tuberculosis are more insidious than those of any of the venereal diseases, and early treatment more important.

Until some super prophylactic drug which can be taken by mouth comes along, legalized and controlled prostitution, as was carried on until recently in France, is the only safe method of V D control. The termination of this system in France has led to an increase in V D. The relaxation of official harshness manifested in the adoption of such a system would also do much to establish a healthier outlook on sexual matters, and a more sensible attitude to V D. A quotation from *Sex, Life and Faith* by Rom Landau is appropriate, "The number of divorces for sexual misdeemeanour is much smaller in France than in Great Britain—they have suffered far less from neuroses or sexual aberrations. Evidently their more frank and natural approach to the problem of sex is to some extent responsible"—I am, etc,

Edinburgh

W B LAING

### Confidential V D Treatment

SIR—By her complaint against the Minister of Health for removing the statutory requirement of secrecy about V D Miss Katharine B Hardwick (Aug 7, p 313) fails to see the wood for the statutory trees and betrays signs of a legalistic mind out of touch with realities.

When in 1916 the V D service was started the Government accepted the recommendations of the Royal Commission on Venereal Diseases that attendance should be voluntary and free, but added a statutory requirement of secrecy which was not one of the Commission's recommendations. No doubt this addition was made for propaganda purposes to beguile an unprepared and possibly distrustful public into voluntary attendance at V D clinics. No doubt also the provision was inserted in deference to the fears of those who thought that the public would not regard public clinics as sufficiently private and that therefore V D would still be treated inefficiently in an underground manner by unqualified persons.

Whatever the reasons for inclusion of the provision of statutory secrecy there is no doubt that after more than thirty years of experience of the V D service the public is firmly convinced that the staffs of V D clinics do in fact maintain the greatest secrecy, and few members of the public who use the V D clinics are as well informed as Miss Hardwick about the legal background or as impressed by its power.

Having worked in V D clinics for many years I have no hesitation in emphatically stating that the high standard of secrecy and confidence obtaining in these clinics is due neither to statute (as she asserts) nor to Ministerial hopes (as she agrees), but to the sense of responsibility and loyalty of the medical and lay staffs, who have learned during more than thirty years' experience the great importance of securing the trust and confidence of their patients. Secrecy is now so strongly entrenched by custom in the minds of public and clinic staffs alike that a statute is unnecessary to buttress it. Rather than complain that a Minister of a Socialist Government revokes regulations we should congratulate him and those who advised him for removing unnecessary legal lumber.

Finally, by encouraging ventilation of the Minister's revocation of statutory secrecy Miss Hardwick is tending to obtain the very opposite of what she wants. If she saves from the mountain tops that there is now no secrecy about V D (because it is not statutory) not only is she publishing error not only is she casting an unwarranted slur on the devoted staffs of V D clinics but she is herself likely to cause unfounded doubts to arise in the minds of the very public she wishes to protect—I am, etc,

London NW 5

F R CURTIS

### Thiouracil in Treatment of Thyrotoxicosis

SIR—We should be grateful to Professor H P Himsworth (July 10, p 61) for his lucid exposition of the status of thiouracil in the treatment of thyrotoxicosis. For more than a year I have taught that white counts are not a routine necessity in thiouracil therapy, but that they should be done in the three following circumstances: (1) In the first few weeks of treatment they are valuable in order to detect the occasional case in which granulopenia reaches a dangerous level. It is helpful to know the usual white cell level of each patient, for this varies greatly in different individuals (my own white count is usually between 4,000 and 5,500 with about 50% to 60% of polymorphs) and it is correspondingly difficult to generalize regarding the level of granulopenia. (2) A white count should be done whenever the minor toxic effects of thiouracil appear. By themselves these manifestations do not call for cessation of the drug, it is the level of the white count that matters. (3) Agranulocytosis. I fully agree with Professor Himsworth that routine white cell counts are no safeguard in preventing or detecting this dangerous complication.

I believe that the quickest way of dealing with a suspected case of agranulocytosis is to make a thick film of peripheral blood as is done in the diagnosis of malaria and stain it with Field's stain—a few seconds' gentle agitation in solution A then in distilled water, then in solution B, and finally in water again. Anyone can make a good thick film if they trouble to practise, and most people should be able to distinguish a polymorph in a thick smear. Given a microscope and the necessary stain (which

## Non-astringent Iron COLLIRON

A highly concentrated colloidal iron hydroxide, representing the equivalent of 10% metallic iron

Colliron replaces with advantage all the older forms of pharmaceutical iron, as it is readily assimilated non constipating and does not aggravate the digestive troubles which frequently accompany the anæmias

Colliron is well adapted for use in chronic microcytic anæmia of women, especially during pregnancy, in secondary anæmia following hæmorrhage, in the anæmias of infants and children and in all debilitated conditions wherever iron is necessary

Issued in bottles of 4 fl oz.  
8 fl oz 40 fl oz & 80 fl oz.

### The time, the place —and the Portanaest

It means much to the General Practitioner to know that the Portanaest is always at hand, equally ready for midwifery in the home and minor surgery in the consulting room or factory. Completely portable, it is very compact yet leaves nothing to be desired in the completeness of its equipment or the easy facility of its use. A master knob controls the rate of flow and pressure, another controls the mixture which can be read from the dial at a glance. For dentistry, the Portanaest can best be described as a portable "Walton"—an indispensable part of a visiting practitioner's equipment. A demonstration will be gladly arranged. Literature is available on request.

### Dietetic Treatment of Hepatic Cirrhosis

SIR—In the leading article under the above heading (June 5, p 1089) you suggest among other considerations the use and clinical test of antithyroid drugs in the treatment of human hepatic cirrhosis. It is a pleasure for us to let you know briefly about our work in this subject since 1946. We used thiouracil in 11 cases of human cirrhosis based on the works of Gyorgy and Goldblatt (*Science*, 1945, 102, 450). These authors demonstrated that the addition of thiouracil in the cirrhosis diet for rats plays a powerfully preventive role. In our group of patients the drug was used in amounts of 0.6 g per day with a total dosage which fluctuated between 3.6 g and 20.4 g.

In order to estimate the effects of this treatment three groups of cirrhotic patients of the same condition were studied—one group (the control) with hydrocarbonate diet, glucose, serum, and paracenteses, a second with a hyperprotein diet and vitamin B complex, and a third with hyperprotein diet, B complex, and thiouracil. The results of these different systems of therapy are summarized in the following table.

Group	No. of Cases	Better	Results Same	Worse
I	9	1 (11%)	4 (44.5%)	4 (44.5%)
II	17	7 (41%)	4 (24%)	6 (35%)
III	11	7 (63.6%)	1 (9%)	3 (27%)

### Liquid Paraffin in Baking

SIR—In the leading article entitled "Liquid Paraffin Risks" (June 12, p 1141) mention is made of the potential dangers inherent in the use of medicinal paraffin and other less refined mineral oils in baking. The work of Frazer and his colleagues indicating the possibility of liver and other damage due to mineral-oil absorption when ingested as finely dispersed emulsions of particle size less than  $0.5 \mu$  is reported, and comment is made on the lack of information regarding mineral oil distribution when dispersed in flour products, such as cakes and pastry, baked with liquid paraffin as a replacement for vegetable fat.

We have recently examined some emulsions containing mineral oil before and after heating, the unheated emulsions containing particles ranging in size from less than  $0.5 \mu$  to  $10 \mu$  or greater. On heating, the individual oil particles coalesce, forming larger aggregates, until ultimately the emulsion is completely broken into two layers. It might be anticipated therefore that, after incorporation of liquid paraffin in a cake batter, on baking the emulsified material would break down and no particles would remain in the final product less than  $0.5 \mu$  in size. This supposition is not, however, in accord with the observations herein reported. Examination, using a Reichert optical system, of sponge-batter smears containing liquid paraffin, baked in a micro-oven (to be described elsewhere) and under continuous observation on a glass screen, indicated that although some aggregation of the initially finely dispersed liquid paraffin did occur there still remained in the final product some particles approximately  $0.5 \mu$  in size. The smears under examination were taken from a bulk batter composed of cake flour 14 g, sugar 10 g, dried egg 3 g, baking powder 1 g, water 10 ml, and liquid paraffin 15 ml. A red, oil-soluble, water-insoluble dye was used to colour the liquid paraffin in order to differentiate it from the other constituents of the batter. Magnification was 600 diameters and the observation screen had a scale etched thereon so that direct observation of particle size could be made.

In the experiment quoted some 30% of the total number of liquid paraffin particles present in the uncooked batter were about  $0.5 \mu$  in size, and although this percentage was con-

siderably reduced after baking some very small particles were still clearly discernible. It should be noted that the actual weight percentage of the original mineral oil used that would exist in this fine state of subdivision would be extremely small, and it might be claimed that even on continuous ingestion over long periods absorption of sufficient oil likely to cause liver damage might not occur. Nevertheless the very existence of a number of small particles which come within Frazer's classification as potentially liable to cause liver damage suggests the desirability of ascertaining whether there exists a threshold limit to their number before damage becomes real.

The work of Alvarez<sup>1</sup> indicates, however, that the fine emulsification necessary for liver damage can be effected by the bile acids, oleic acid and glyceryl monostearate, which may be found in the bowel. In this connexion it should not be overlooked that glyceryl monostearate is a common emulsification agent and is, in fact, now used in the preparation of certain foods. It would appear therefore that, even though the number of particles of mineral oil of size less than  $0.5 \mu$  appears to be considerably reduced on baking, this may be immaterial inasmuch as subsequent ingestion may well restore the level of such particles to the original value. Further physiological investigation on these points is clearly desirable, as the problem would appear to be of even wider significance than the editorial previously referred to implies—We are, etc.,

### Comprehensive Child Health Service

SIR—Dr H R Youngman's letter (Aug 7, p 313) stirs me to comment on the recent correspondence on this subject. A high percentage, I should say the majority, of complaints for which the child is brought to the doctor these days are described as behaviour problems—e.g., feeding problems, sleeplessness, bed-wetting, etc. These are usually the result of home conditions and parental mismanagement. How can a "clinic" doctor appreciate these conditions unless he has an intimate knowledge of the complete home picture and of all its members? To abolish the general practitioner would be to kill the root and main stem of medicine—its specialist branches would then soon wither and die.

What we want are more general practitioners with better undergraduate training in paediatrics, who have time to know and understand the home life of their patients so that with the aid of improved housing conditions and social services behaviour problems can be more easily corrected or even prevented. Then we shall find the paediatric specialist will be superfluous—I am, etc.,

London NW 7

C ELAINE FIELD

### Geriatrics

SIR—The first supplement to the report of the B M A Committee on the Care and Treatment of the Elderly and Infirm (Aug 7, p 71) contains several interesting recommendations for the solution of the chronic-sick problem. However, one important point seems to have been overlooked—this is the need to train more doctors in the special techniques which have been evolved by such hospitals as the West Middlesex, Orsett Lodge, and St John's, Battersea. It is probably true to say that a hemiplegic patient treated by Dr Marjory Warren's methods has a better chance of complete recovery than one not so rehabilitated. A patient with incontinence of urine is just another bed-wetter in hospitals where Dr Thomas Wilson's cystometric technique is unknown. A chronic arthritic treated by Mr Grant Waugh's procaine-lactic acid injections has prospects of improvement undreamt of by those who have not used this method.

In the same way the rehabilitation of elderly patients can reduce the number of bedfast patients considerably, as mentioned in the report.

Why does the Ministry of Health take no steps to make this special knowledge available throughout the country? The discoverer of a new form of treatment for cancer would probably be given every facility for making his techniques known.

all over the world. Yet in this country the chronic-sick problem is even more pressing. General practitioners sometimes have to strain the truth in order to get their elderly patients admitted to hospital. Nursing staff avoid "chronic" hospitals in which active treatment followed by recovery is unusual. A training school of geriatrics would not be likely to suffer in this way from shortage of staff. We have had many hospitals for children, and now there is a postgraduate institute of paediatrics where specialists in this branch of medicine are trained. What about a hospital for the elderly and a postgraduate centre for geriatrics?—I am, etc.,

### Medicine in General Practice

SIR—It would be interesting to know if Dr D V Hubble, who reviews (Aug 7, p 301) Dr R P McCombs's *Internal Medicine in General Practice* is himself engaged in general practice. He finds fault with the book because only half a page is devoted to cerebral tumour. I can recall only one case of intracranial tumour encountered in twenty years as a G.P. This baffled the diagnostic acumen of at least one consulting surgeon and one consulting physician. Another consulting physician suspected the condition. He referred the patient to a neurosurgeon, who failed to localize the tumour after full investigation at a special clinic. I sent the man to a hospital of international fame, where he lay for months before a sufficiently accurate diagnosis to permit operation could be made.

It seems strange to me, as a general practitioner, to expect a textbook of this kind to be devoted to any more detailed consideration of diseases of the nervous system than can be encompassed in one eighteenth of its volume. The vast majority of these diseases are incurable, and all the G.P. can usually do is to ask a consultant to announce the verdict to the patient. Certainly diseases of the nervous system do not form one eighteenth or even one one-hundredth of our daily work.

There may be areas in this country where the cost of x-ray investigation has not hitherto precluded its use as a "nearly routine measure" in gastro-intestinal disorders, but it would be by no means true of the country as a whole. The G.P. must in the first instance refer his poorer patient to the appropriate out-patient department, where the physician or surgeon in charge decides as to the necessity or otherwise of x-ray examination. One greatly doubts if the dawn of the Bevan era means that the G.P. will be able to use full x-ray study as a nearly routine measure for his patients—I am, etc.,

DONALD M O'CONNOR

### POINTS FROM LETTERS

#### Service Doctors in Far East

Lieut-Col LENNOX R S MACFARLANE R.A.M.C. (Tripoli), writes. I was amazed at the unfairness and onesidedness of Lieutenant D R Morgan's letter (July 3, p 54). In fairness to your readers let me put the other side of the question. The "regular" who has no "difficulty in obtaining a passage" has to wait in any foreign station at least six months before he can get his family out and live "in comfort if not luxury." Moreover this happens at frequent intervals and will continue to do so while there is a shortage of quarters, and this is in addition to the many years' separation most R.A.M.C. regulars had to go through during the war. Also when the regular goes home for a short spell he goes to a station where there is another six months' delay in finding a house. If the "conscript," as Dr Morgan chooses to call him, were to have equal rights in quarters and passages he and the regular would have to wait at least a year to get their families out, which would be most unfair to the regular who has taken the job on voluntarily and of little use to the conscript who is only abroad for 18 months.

#### Fibrositis

Dr CYRIL HELM (Plymouth) writes. I was interested to read the article by Dr James Cynax on fibrositis (July 31, p 251). When I came to Plymouth about a year ago, I was astonished to find that a large number of my patients were suffering from fibrositis or muscle spasm, call it what you will. Some of the cases were due to articular displacements, but the majority definitely were not. The climate here is humid and muggy, and this must have some bearing on the matter. A fair proportion of these cases are women who are tired and anxious. Physiotherapy and drugs are of little avail, but a good holiday or a week in bed, with plenty of sleep, cures the majority of them.

## Obituary

### JOSEPH CUNNING, M.B., F.R.C.S.

Mr Joseph Cunning died at his home in Reigate on July 29 at the age of 76. He was senior surgeon at the Royal Free Hospital from 1919 to 1931.

Joseph Cunning was a son of the late James Erskine Cunning, and he was born in Victoria, Australia. He was educated at Ballarat, the University of Melbourne, and St Bartholomew's Hospital, London. His association with the Royal Free Hospital began in 1901 when he became the senior resident medical officer, in due course he was elected to the honorary staff, and in 1919 became the senior surgeon of the hospital, which position he held until his retirement in 1931. He was also surgeon to the Royal Cancer Hospital and the Victoria Hospital for Children, and a president of the Australian and New Zealand Association of Medical Men in England.

Mr Cunning was a man of great personal charm, kindly and debonaire, and he filled the post of senior surgeon to the Royal Free to the enhanced reputation of the hospital. He was wise in counsel, tolerant in judgment and criticism, and possessed of a kindly wit and great sense of humour which endeared him to his colleagues. His surgery was an art and a delight to watch—he was always cool and imperturbable, bold in design and skilful in execution. He was a great teacher, always ready and willing to help his juniors by advice, example, and assistance. There are many surgeons to day who owe their skill and experience to Mr Cunning's unfailing kindness and help, and they will remember with gratitude their debt to him.

Although Mr Cunning was a general surgeon, his chief interest was in the surgery of the upper abdomen. In the days when gastric surgery was in its infancy he was, as he himself expressed it, an ardent gastrectomist. He was the author of many papers on surgical subjects. The first three editions of *Aids to Surgery* (from 1904 to 1913) were from his pen.

After his retirement from the Royal Free Hospital Mr Cunning gave up surgical practice completely and retired to Broome Park, Betchworth, Surrey, where he transferred his interest and skill to the cultivation of irises and other gardening activities. Mr and Mrs Cunning in 1946 gave this lovely house and grounds to the Electrical Industries Benevolent Association as a home for old people, to serve as a memorial to their son, James Erskine Cunning, who was killed in action in 1941. Mr Cunning is survived by his wife—herself a medical woman and a Royal Free Hospital graduate—and by two sons and one daughter, who has followed in her parents' footsteps. To all of them sincere sympathy will be extended by all who knew and loved Mr Cunning—G B.

Miss K G Lloyd-Williams writes. Past students of the London (Royal Free Hospital) School of Medicine for Women have heard with sorrow of the death of Joseph Cunning. We knew him as a first-class surgeon and teacher, and his early retirement from surgery in 1931 was greatly regretted. His punctual arrival in the quadrangle, immaculately dressed, with buttonhole and cigar just at its last inch, was the prelude to a round in which in an apparently informal way he imparted a wealth of information. His humorous anecdotes enlivened the afternoon and served to impress salient facts on his audience. In his own inimitable way he was in the first rank of teachers. A versatile and amusing companion, he was the ideal mentor for young residents, who learnt much from his humane outlook on life.

As an operator he was outstanding, more especially in the field of abdominal surgery. The first to acknowledge and appreciate skill in others, one of his most engaging qualities was his modesty about his own work. He gave no appearance of haste or showmanship, but his results testified to his high skill. He was deeply attached to the Royal Free Hospital, and its welfare was always very near to his heart. He gave the hospital service of the highest order, and we all remember him with affection and pride.

## W C ALLARDICE, M.D, F.R.C.S.E.D

We announce with regret the death at the age of 77 on Aug 2 of Dr W C Allardice, honorary consulting surgeon to the North Staffordshire Royal Infirmary

William Clachan Allardice was educated at Bon Accord, Aberdeen, and Glasgow University. He qualified M.B., C.M. in 1892, and took his M.D. of Glasgow four years later, in 1906 he took the F.R.C.S. of Edinburgh. After qualification Allardice was house surgeon at Macclesfield General Infirmary, and subsequently house-surgeon and then house-physician at the North Staffordshire (now Royal) Infirmary. At one time he was resident clinical assistant to the Montrose Royal Asylum. At the turn of the century Dr Allardice went into partnership at Newcastle-under-Lyme with the late Dr G S Hatton, and remained in the same practice until he retired in 1945. In 1902 he became honorary assistant surgeon to the North Staffordshire Royal Infirmary, and subsequently honorary surgeon and orthopaedic surgeon to the same institution. When he retired from the active list under the infirmary's age regulation in 1930 he became honorary consultant surgeon. For many years he was also consulting surgeon to the Congleton War Memorial Hospital, and during the war of 1914-18 was surgeon to the London Road Military Hospital at Stoke-on-Trent. Dr Allardice contributed a number of articles to the medical press, his earliest being one to the *Glasgow Medical Journal* in 1896 entitled "Notes on 1,500 Cases of Anaesthesia." He joined the B.M.A. in 1895, was a representative in 1922, and president of the Staffordshire Branch 1926-7, he was also chairman of the North Staffordshire Division 1933-4. Dr Allardice had a successful career as a general practitioner surgeon, and it was due to him that the Orthopaedic Department and the Ear, Nose, and Throat Department were established at the North Staffordshire Royal Infirmary. By his first wife, who died in 1903, he had one son, and by his second wife, whom he married in 1911, he had two sons and two daughters. He won the affection and esteem of those among whom he lived and worked, and inspired confidence in his patients and respect among his colleagues as a man who gave of his best to his chosen profession. He was a justice of the peace for Newcastle-under-Lyme and was at one time Mayor of Hanley. A large gathering paid their tribute to his memory at the funeral held at St George's Church, Newcastle.

R. A. K. writes: Bill Allardice, as he was affectionately known by a host of friends, qualified from Glasgow University at the age of 21. He was a most able and conscientious surgeon and had developed a clinical sense and balance of judgment to an extraordinarily fine degree. He was the perfect example of the ideal family doctor—a most trusted friend, unfailing in his help and understanding of personal problems. His stately bearing and kindly smile inspired thousands of his patients with supreme confidence and trust. He realized full well the inestimable value of a good family life and devoted all his energies to that end. He was, indeed, a revered husband, father, doctor, and friend. To his widow, two daughters, and three sons the deepest sympathy is extended by all who have been fortunate enough to have known this grand old man.

Dr STEPHEN JOHN HENRY died suddenly at his home in Glasgow on July 20 at the age of 62. He studied medicine at Glasgow University and graduated M.B., Ch.B. in 1908. After holding resident hospital appointments he went into general practice in the Partick district of Glasgow in 1910. During the war of 1914-18 he served in France with the 70th Field Ambulance. He resumed general practice after the war and held several appointments, including membership of the Disabled Persons Advisory Panel in Glasgow. He was a former president of the Partick and District Medical Society. He leaves a widow, two sons, one of whom is a medical student, and two daughters.

Dr HUGH COLLIN DAVIES died at his home in Colwyn Bay on July 29. He was born in Carmarthen in 1878 and was educated at University College, Cardiff, and Glasgow University. He graduated M.B., Ch.B. in 1903. He spent many years in practice in South and West Wales, and served in the R.A.M.C. in the first world war. He took his M.D. Glas. in 1925 and joined the staff of the Welsh Board of Health as Regional Medical Officer the same year. His long experience as a general practitioner enabled him to carry out his official duties in an outstanding way. Dr Davies was known to medical practitioners

throughout Wales as a kind friend, and patients referred to him were sure not only of sympathetic consideration but also of a first-class opinion. During the last war he was seconded by the Welsh Board of Health to the Emergency Hospital Service, and he became Hospital Officer for North Wales. As such he was responsible single-handed for organizing the emergency service throughout the six counties of North Wales. There is no doubt that the efforts he made during the war, which came at a time of his life when he was past his prime, must have contributed to the ill-health from which he suffered after his retirement in 1945. The sympathy of all who knew him will be extended to his widow.

Dr GEORGE ANDREW, who was probably the oldest living Fellow of the Royal College of Surgeons, died at Brighton on July 29 at the age of 96. He was born in Devonshire and studied medicine at St Bartholomew's Hospital. He qualified in 1874 and took his F.R.C.S. in 1879 and his M.D. Durh. in 1893. He practised in Egham, Gravesend, Torquay, and finally in Monte Carlo. To the end of his life he retained the full use of all his faculties, and he was renowned among his relations and friends for his amazing memory. He will be greatly missed by all who knew him.—L. G.

Dr EDWARD LIONEL MACPHERSON RUSBY died suddenly at his home in London, S.W.2, on Aug 1, at the age of 76. He was a student at King's College Hospital and qualified in 1896. He graduated M.B. two years later. After a short assistantship in general practice in Bromley he joined up with many other members of the Honourable Artillery Company as a private in the Civil Imperial Volunteers and served in the Boer War. He was later promoted Civil Surgeon in the South African Field Force. On his return to this country he settled in Brixton and built up a large practice as well as a quite considerable reputation as an obstetrician. He was honorary medical officer to the Water Lane Dispensary, district medical officer, and public vaccinator for Lambeth. This last appointment he retained until July 5 of this year. He was a member of the British Medical Association throughout the whole of his professional life, and for several years was honorary secretary of the Lambeth Division. He was a keen athlete in his younger days, and he led a full and active life until the morning of his death. His wife predeceased him by six months. He leaves a son and a daughter.

Dr RICHARD HENRY WACE died in London on Aug 5 at the age of 80. He studied medicine in Aberdeen and graduated M.B., C.M. in 1894. He had a varied medical career having been coroner among the aborigines in the Northern Territory of Australia and medical officer in the Falkland Islands where he did his round on horseback, once even covering a hundred miles in a single day. In spite of failing health he continued in active practice until he was 78. During the last war Dr Wace turned earlier experience in a mental hospital to good effect by acting as locum tenens in mental hospitals. Dr Wace was of distinguished appearance and his manner was charming and courtly. He dearly loved a classical allusion. He was proud of his 800-year-old descent from the Anglo-Norman poet Wace or Eustace, of Jersey. He was a capable artist. He leaves a widow and a son.—E. S. S.

## Medico-Legal

### DAMAGES AGAINST A MEDICAL OFFICER OF HEALTH

[FROM OUR MEDICO LEGAL CORRESPONDENT]

A recent Irish case shows that when a medical officer of health, in attempting to protect the public against suspected carriers of typhoid, orders them to be discharged from employment he cannot be too careful to protect himself by observing all the regulations. Miss Annie O'Connor had been a cook on an Irish train. On June 29, 1944, a number of diners contracted typhoid fever, and Miss O'Connor herself caught the disease on July 21. She made a full recovery and was discharged cured. In March, 1945, she became assistant cook in the Grand Hotel, Greystones. In May a number of persons brought actions against the railway company but failed to establish negligence. On May 19, at the order of Dr Gerald P. G. Beckett, medical officer of health of County Wicklow, she was discharged on suspicion of being a "precocious" typhoid carrier. (As was explained later, this word should have been "chronic" or "intermittent.") She sued him and the county council for negligence and breach of duty, an allegation of libel and slander against the doctor was

withdrawn<sup>1</sup> The evidence showed that he made no tests when ordering Miss O'Connor to be discharged, and that afterwards three tests made at weekly intervals were negative. He did not carry out the regulation that in such a case a medical officer must give notice in writing to the employer that he considers it necessary that the suspect should submit to medical examination.

Miss O'Connor said in evidence that she was called to the private room of the manageress and asked by Dr Beckett if she had had typhoid fever, she replied that she had, but had been discharged with a clean bill of health. Later the manageress sent for her and read out a letter from the doctor saying that she was possibly a precocious carrier of typhoid and must not on any account be employed in any position connected with the preparation or handling of food, she would therefore have to leave at once with a week's wages. The letter was a terrible shock to her. She took a post as a waiting-room attendant, and was offered one as a cook but was afraid to take it up. She was waiting for the case to clear her before she applied for another. No one associated with her or in contact with her had contracted typhoid. Miss Mary Loughnane, the manageress, gave evidence that Dr Beckett, at his visit to her, did not seem to know what to do. He did not want to take the girl from employment, but at the same time wanted to do his duty. He rang up the hospital where the girl had been treated, and, judging by his answers, seemed to get no choice in the matter. He then said he was afraid she would have to let the girl go, and sent her the official letter.

Dr C J McSweeney, chief medical officer of the fever hospital where Miss O'Connor had been a patient, said that before and after her discharge the usual tests were carried out and proved negative. That, however, did not necessarily mean that the outbreak on the train had not been due to a member of the staff. He had come to the tentative conclusion that the carrier had been Miss O'Connor. When Dr Beckett asked him for information about Miss O'Connor, he said that it would be risky to keep the girl on without a check. Even a negative result would not enable anyone to certify her free from the danger of disseminating typhoid. She was an unsuitable person to employ as a cook. In the hospital she had had an unhealthy gall-bladder, and that predisposed to a carrier state. Women were five times as liable as men to become chronic carriers. It was difficult and tedious to clear a person conclusively of being a carrier, sixteen negative tests might be followed by a positive. Even now Miss O'Connor might be clear for three years and then give a positive result. The control of carriers was the hard core of the problem of prevention. A person undergoing test should not be employed in the preparation of food.

Professor J W Bigger, of Trinity College, Dublin, said that no examination at the hospital on the date of Miss O'Connor's discharge would have disclosed whether or not she was a chronic carrier, considering that it had taken three days with all the facilities of the laboratories to carry out the tests he had done in the case. The tests made at the hospital and after Miss O'Connor had left it were conventional but quite inadequate. In answer to the judge he said that it would have been proper to give the girl warning when she left hospital, compensate her amply, and take precautions to see that she was never allowed to handle food until an investigation had been carried out. "In practice, it had better be a life sentence."

Dr Beckett said in defence that when he received a letter from the medical officer of health for the city of Dublin about Miss O'Connor he considered that it required immediate action. Dr McSweeney told him that an investigation had pointed to Miss O'Connor as the cause of the outbreak on the railway. He told Miss Loughnane that Miss O'Connor must not be employed in connexion with food, but he very definitely did not say that she must be sacked. He had no objection to her doing a job which did not involve the handling or preparation of food. There was no time for an examination, he felt it his primary duty to stop her from acting as a cook.

Dr James Deeney, chief medical officer of the Department of Health, said it was a tribute to the public health officers that they had achieved a great reduction in the incidence of typhoid under practically unworkable and misleading regulations. The medical officer had practically no power. Dr Beckett could not

have prevented the girl from cooking without taking her to court.

Mr Justice Maguire ruled that Dr Beckett was for this purpose a statutory officer, responsible for the enforcement of the regulations to the Minister for Local Government and Public Health, and not the servant of the county council. Summing up for the jury, he said that no legal justification had been put forward for the dismissal of Miss O'Connor at the request of Dr Beckett without warning. A strange feature of the case was that Miss O'Connor had been given no warning when she left hospital about the danger of her handling or preparing food. It also seemed a little strange that the public authorities responsible for the prevention of typhoid should not be a little more careful, possibly if they were they would have a little less trouble. Miss O'Connor had not been a party to the inquiry about the railway outbreak, and could not be bound by any decision taken at it. The jury found that Dr Beckett had been negligent and awarded £750 damages.

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

† Deaths from measles and scarlet fever for England and Wales London (administrative county) will no longer be published

‡ Includes primary form for England and Wales London (administrative county) and Northern Ireland

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales London (administrative county) are combined

|| Includes puerperal fever for England and Wales and Eire

## EPIDEMIOLOGICAL NOTES

## Discussion of Table

In England and Wales infectious diseases were less prevalent during the week. There was a decrease in the incidence of scarlet fever 418, measles 290, whooping-cough 50, acute pneumonia 30, dysentery 31, and diphtheria 14, while an increase was recorded in the notifications of paratyphoid fever 26 and cerebrospinal fever 15

A fall in the notifications of scarlet fever occurred throughout the country, the largest fall was 75 in Lancashire. The largest decreases in the incidence of measles were London 95, Durham 81, and Essex 73, the largest rises were Yorkshire West Riding 192 and Gloucestershire 67. The chief variations in the returns for whooping cough were falls in Middlesex 83, Yorkshire West Riding 55, and Durham 53, with rises in Cheshire 56 and Sussex 42

The notifications of diphtheria (125) reached the lowest level yet recorded and were 9 below the preceding lowest level. The largest variations in the returns for diphtheria during the week were a decrease of 10 in Yorkshire West Riding and an increase of 9 in Cheshire

The largest returns for dysentery were London 24 Lancashire 11, and Yorkshire West Riding 10. Paratyphoid fever reached the highest level for almost a year, the two principal centres of infection were Northamptonshire 14 (Corby U D 10) and Sussex, Eastbourne C B 10

Notifications of acute poliomyelitis have been practically constant during the past three weeks. Multiple cases were notified during the week from London 6 (Westminster 4), Middlesex 5 (Heston and Isleworth U D 2, Wood Green M B 2), Yorkshire West Riding 4, Yorkshire East Riding 3 (Kingston-upon-Hull C B 2), Southampton 3 (Southampton C B 2), Lancashire 3 (Warwickshire 2, and Yorkshire North Riding 2)

In Scotland a decreased incidence was recorded for scarlet fever 37 acute primary pneumonia 29, dysentery 17, and measles 11. Of the 35 cases of dysentery 25 were notified in Glasgow. Notifications of cerebrospinal fever increased from 10 to 17, and of these cases 14 were notified in Glasgow

In Eire a fall occurred in the notifications of whooping-cough 21, measles 16, and diarrhoea and enteritis 12. The largest outbreak of measles during the week was at Monaghan Castleblayney R D 30

In Northern Ireland the only fluctuation in the trends of infectious diseases was a decrease of 23 in the notifications of scarlet fever

## Quarterly Returns for England and Wales

During the first quarter of the year the births were equivalent to a rate of 18.9 per 1 000, which was 3.9 below the rate for the March quarter of 1947. Infant mortality was 41 per 1,000 live births and was the lowest rate ever recorded in a first quarter, being 11 below the rate for the first quarter of 1947 and 25 below the average rate for the March quarters of the 10 preceding years, 1937-46. The general death rate was 12.4 per 1,000 the lowest rate ever recorded for a March quarter. It was 4.7 below the rate for the first quarter of 1947 and 1.9 below the average of the first quarters of the five years 1942-6. Only 644 deaths were attributed to influenza the lowest number previously recorded in a first quarter was 1,470 in 1945. The ten-yearly average of influenza deaths for the first quarters of 1938-47 was 3,800

## Quarterly Returns for Northern Ireland

During the first quarter the birth rate was 22.1 per 1,000, which was 1.2 below the average rate for the five preceding first quarters. Infant mortality was 53 per 1,000 registered births compared with an average rate of 78 for the corresponding quarters of the five preceding years. Maternal mortality was 2.4 per 1 000 births and was 0.5 below the five-year average. The general death rate was 12.8 per 1,000 and was 3.3 below the average rate for the first quarters of the five preceding years. Deaths attributed to the principal epidemic diseases numbered 92 and included 43 deaths from influenza, 26 from diarrhoea and enteritis in children under 2 years, and 16 from whooping cough. Deaths from pulmonary tuberculosis numbered 207, and there were 44 deaths from other forms of tuberculosis. These totals were 39 and 30, respectively, below the average of the first quarters of 1943-7

## Week Ending August 7

The notifications of infectious diseases in England and Wales during the week included scarlet fever 848, whooping cough 3 185 diphtheria 107, measles 6 879, acute pneumonia 363, cerebrospinal fever 40, acute poliomyelitis 38, dysentery 111, paratyphoid 47, and typhoid 10

## Medical News

### Tuberculosis in Scotland

The Secretary of State for Scotland has asked the Scottish Health Services Council to assist him in making a special examination of the tuberculosis position in Scotland, and the Council has set up a special committee for this purpose. The committee includes three members of the Council—Captain J P Younger, of Alloa, who is chairman of the committee, Dr Matthew Fyfe, Medical Officer of Health of Fife County, and Dr J R Langmuir, a general practitioner in Glasgow. The other five members of the committee are Professor Cameron, Professor of Tuberculosis in Edinburgh University, Professor Crew, Professor of Public Health in Edinburgh University, Dr H C Elder, who is in charge of mass radiography in Edinburgh, Dr S I A Laidlaw, medical officer of health of Glasgow, and Dr Maclean, who is in charge of mass radiography arrangements in Glasgow.

### British Tuberculosis Association

At its recent annual general meeting the Tuberculosis Association decided to change its name to the British Tuberculosis Association.

### Waste Straw

Professor S Zuckerman, of Birmingham University, has been appointed head of a Government committee to find a use for waste straw.

### Sir Harold Gillies

The King of Norway has conferred the decoration of Commander of the Order of St Olav upon Sir Harold Gillies in recognition of services rendered during the war.

### Psychotherapeutic Conference

From Aug 3 to 9 psychiatrists and psychologists from Australia, Chile, China, Denmark, Finland, France, Holland, Norway, Sweden, Switzerland, South Africa, the U.S.A., and Great Britain took part in an international technical psychotherapeutic conference at the Institute of Child Psychology, this was complementary to the International Congress on Mental Health. At the close of the conference the possibilities were discussed of reuniting the links formed at the conference between child psychiatrists and psychologists in an informal international association of national groups.

### Tribute to Pharmaceutical Society

The Minister of Health paid a tribute to the Pharmaceutical Society when he was the Council's guest at their monthly dinner on July 27. They had always got on well together, he said, and it was a fact that the discussions with the pharmaceutical profession had been more fruitful than with any other branch of the medical world. This great scheme had many tributaries, and the pharmaceutical was not the least of them. It would be almost impossible to launch a ship of the size of the National Health Service without considerable water displacement. Other countries were watching us. Britain had not been exhausted by 6½ years of war, we had been inspired by the war and our energies had hardly been tapped.

### Wills

Sir George Newman, of Grims Wood, Harrow Weald, late Chief Medical Officer of the Ministry of Health, left £58,618. Professor Henry Arthur Burgess, of Cheshire, President of the B.M.A. in 1929 and for many years Professor of Clinical Surgery in Manchester University, left £122,276 3s 9d. Dr Henry Willoughby Gardner, of Church Stretton, Salop, left £68,120 16s 6d.

## COMING EVENTS

### Physical Medicine

A short course of lectures on the various aspects of physical medicine has been arranged on Tuesdays and Thursdays at 5 p.m. from Sept 2 to Oct 7 inclusive, and will be suitable for candidates preparing for Part II of the Diploma in Physical Medicine. Further details can be obtained from the honorary secretary, British Association of Physical Medicine, 45, Lincoln's Inn Fields, London, W.C.2.

### Conference on Infertility

The annual conference on infertility, organized by the Family Planning Association (69, Eccleston Square, London, S.W.1), will be held at Exeter on Saturday and Sunday, Sept 25 and 26. A draft programme has been arranged as follows: Sept 25,

10 a.m., "Congenital Absence of the Vas," by Mr D Young, and "Application of the Supravital Stain to Human Spermatozoa," by Dr A C Crooke and Miss Anita Mandl, 2.15 p.m., "Some Lessons from 3,000 Utero-tubal Insufflations," by Dr Albert Shorman, "Hysterosalpingography in Water Soluble Radio-opaque Media," by Miss Josephine Barnes, and "Vitamin E Therapy for Sub-fertility in the Male," by Dr M Hadley Jackson and Dr H A Davidson. Sept 26, 10 a.m., contributions by members of the Royal Free Hospital Sub-fertility Unit. Introduction by Dr Gertrude Dearnley, "The Value of the Sim's Test in the Diagnosis of Male Infertility," by Dr Mary Barton, "Report on a Series of Testicular Biopsies," by Dr E Friedman, "Results of a Series of Testosterone Implants," by Miss M Moore White, "Preliminary Investigation in the Treatment of Oligozoospermia by Vitamin E," by Mr Norman Warren, "The Blood Supply of the Testis and its Relation to Sterility," by Dr R G Harrison, and "The Effect of Dilution on Sea Urchin Spermatozoa," by Lord Rothschild, 2.15 p.m., "The Critical Assessment of Infertility Data," by Dr G I M Swyer, "Coitus and Infertility in the Rabbit," by Dr Harris, "Relationship between Miscarriage and Seminal Characteristics as demonstrated by Seminal Analysis," by Mrs Harvey.

## SOCIETIES AND LECTURES

### Friday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Anatomy Lecture Theatre, Edinburgh University, Aug 27, 3.30 p.m. "Present State of Chemotherapy in Cancer" by Professor A Haddow.

## APPOINTMENTS

BECK, DIANA J. KINLOCH M.B., B.S., F.R.C.S. Neuro surgeon, Middlesex Hospital London W.

JONES D J M.B. B.Ch. D.P.H. Medical Officer of Health for Rugby Borough and Rural District and Area Medical Officer.

MILLAR I B. M.D., D.P.H. Assistant Medical Officer, Newry Division, County Down Northern Ireland.

## BIRTHS, MARRIAGES, AND DEATHS

### BIRTHS

Cleland—On Aug 3 1948 at the Ayrshire Central Hospital Irvine to Joan wife of Mr Gavin Cleland F.R.C.S. Ed. a daughter.

Cowper—On Aug 4 1948 at the Anglo American Hospital Cairo to Grace (née Boxley) wife of Dr S G Cowper a daughter—Ann Christine.

Kennedy—On Aug 8 1948 at Queen Charlotte's Hospital to Minnie wife of Dr Gordon Kennedy of Twickenham a daughter—Ester Margaret.

Paget Davis—On Aug 12 1948 at St John's Hospital Chelmsford to Lillian (née Vaughan) wife of Dr Donald Paget Davis of Braintree Essex a second son—Mark Scot.

Pearsall—On Aug 1 1948 to Mary wife of Dr P R Pearsall Mill Hill London N.W. a daughter.

Pearson—On Aug 13 1948 at St Benda's Nursing Home Bristol to Elise (née Powell) late Q.A.R.N.N.S.(R) wife of Dr G M Pearson a daughter prematurely—Fleur.

White—On Aug 8 1948 at Seely Oak Hospital Birmingham to Edna wife of Mr J R A White F.R.C.S. a daughter.

### MARRIAGES

Gillis—Greaves—On Aug 12 1948 at St John's Wood Synagogue London. Leon Gillis M.B.E. M.B. B.Ch. Orth. F.R.C.S. to Rachel Greaves of Sheffield.

Kendall—Morgan—On June 26 1948 at Huntington Kington Herefordshire Arthur C Kendall M.R.C.P. to Hilda M Morgan M.B. Ch.B.

### DEATHS

Arnold—On Aug 6 1948 at Worthing Miles Bracewell Arnold M.D. D.P.H. late of the Ministry of Health.

Borrowman—Recently Alexander Pierson Robertson Borrowman M.B. Ch.B. of Brampton, Cumberland aged 45.

Brice—On Aug 7 1948 at Thornhill Edge Dewsbury Yorks Henry Doyle Brice M.R.C.S. L.R.C.P. aged 74.

Hounsfield—Recently Maurice Coupland Hounsfield M.B. B.Chir. of Stoke Bishop Bristol aged 43.

Mackie—On Aug 8 1948 while bathing at Sandown Kenneth William Mackie M.R.C.S. L.R.C.P. of Salisbury Green Southampton aged 44.

Maitland—On Aug 10 1948 Thomas Gwynne Maitland M.D. of Hatchmere Wood Norley Cheshire and late of the Cunard White Star Line.

Murray—Recently while on holiday at Dornoch David Alexander Murray M.B. Ch.B. Ed. of Helmsley Yorks.

Nimmons—On Aug 6 1948 Robert Nimmons M.B. B.Ch. of Wheldon House Pelton Co. Durham.

Reckless—On Aug 15 1948 at High Lane near Stockport Cheshire Philip Alfred Reckless F.R.C.S. aged 65.

Sutherland—On Aug 14 1948 at 3 Darnaway Street Edinburgh Francis Benjamin Sutherland M.B. Ch.B. D.P.H. Ed.

Walker—Recently Henry Francis Bell Walker M.D. of Cape Colony South Africa aged 72.

Williams—On Aug 9 1948 at Oakmend Exmouth S. Devon Percy Glyn Savours Williams M.D. late of Cairo.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Suppression and Treatment of Malaria

**Q**—What is the value of 'paludrine' therapeutically and as a suppressive? Can any order of preference be given as between paludrine, mepacrine and quinine for both purposes?

**A**—Paludrine is a valuable drug in the treatment of malarial infections due both to *Plasmodium vivax* and to *Plasmodium falciparum* owing to its lack of toxicity. In acute attacks due to *P. vivax* it will control fever and parasitaemia but will not prevent a subsequent relapse. In acute attacks due to African strains of *P. falciparum* it is slightly slower in its action than either mepacrine or quinine. It will not eradicate *P. falciparum* infections as will mepacrine, and it is not a true causal prophylactic either for *P. vivax* or for all strains of *P. falciparum*. Paludrine is possibly less active than mepacrine or quinine against *P. malariae*.

It is now recognized that paludrine, mepacrine, and quinine have essentially the same action on malaria parasites. In the control of an acute attack paludrine is to be preferred owing to its lack of toxicity. Mepacrine stains the skin and may cause gastro-intestinal discomfort and, in very rare instances, skin lesions and psychotic symptoms. Quinine may cause cinchonism, buzzing in the ears, or deafness. If the infection is due to *P. falciparum* or if *P. falciparum* is the prevailing parasite in the area quinine must be avoided both in treatment and in suppression because of the danger of inducing blackwater fever. If a *vivax* infection is to be eradicated recourse must be had to quinine and pamaquin or to quinine and pentaquine, if a *falciparum* infection is to be eradicated mepacrine will be effective, neither quinine nor paludrine alone will eradicate either *P. falciparum* or *P. vivax* infections. For suppression, the drug chosen must be taken daily. Mepacrine is a better suppressive than quinine for all forms of malaria. Results of controlled investigations into the comparative efficiency of mepacrine and paludrine as suppressives are not at present available.

### Aggenized Flour

**Q**—What is 'aggenized' flour and why has it been adopted for general use both by ourselves and by the Americans?

**A**—'Agene' is the trade name for nitrogen trichloride, which in the pure state is a very unstable compound. It is prepared commercially in impure form by passing chlorine into an aqueous solution of an ammonium salt. A current of air containing about 1% of agene is then passed into the flour, with adequate agitation, until a sufficient quantity has been absorbed. Agene has a strong bleaching action, but it also 'improves' the flour so as to give a tough tenacious dough which bakes into a large porous loaf. Its trade name suggests its function in artificially ageing and maturing the flour. Reasons for the use of agene in preference to other bleaching or improving agents presumably lie in the ease and cheapness of its industrial application and in its efficiency in producing the desired properties in the flour.

### Tuberculous Rheumatism

**Q**—Is the condition of tuberculous rheumatism a definite entity and if so how is the diagnosis established? A boy of 15 had a febrile attack with pain in one knee. Overnight he developed a bilateral effusion in both knees which was painless. Simultaneously he developed erythema nodosum. His temperature fell after three days (he was on salicylates), and the Mantoux reaction was positive in a dilution of 1 in 10,000. No other joints were affected. There is no contact history of tuberculosis. Could this be a case of tuberculous rheumatism and if so is treatment on sanatorium lines indicated?

**A**—In 1902 Poncet described a form of polyarthritis which he believed to be tuberculous, and the 'Poncet' type of rheumatoid arthritis is definitely recognized in France. Reitter and Lowenstein claimed to have isolated the tubercle bacillus

in the blood stream in these cases by a special technique, but others have failed to obtain the same results. Brav and Hench (*J Bone Jt Surg* 1934, 16, 839), after careful study, doubted the existence of a tuberculous form. Copeman (*Reports on Chronic Rheumatic Diseases* 1936, 2, 24) discussed the subject very fully and described cases which appeared to be tuberculous. On the whole it seems probable that the tubercle bacillus may be responsible for some cases of polyarthritis of the rheumatoid type.

The case described in the question does not, however, appear to be of this character, and such a diagnosis could not safely be reached at this stage. Careful observation over a long period would be required, and the first step should be an exhaustive search for any possible tuberculous focus in the body, possibly glandular. At a later stage, if the signs persisted, joint biopsy might be justified. The positive Mantoux reaction might be due to a healed focus, possibly calcified glands, without necessarily being associated with the joint attack. Erythema nodosum may be tuberculous or streptococcal in origin, or may occur without evidence of either, though a tuberculous infection is believed to be a predisposing factor. Subacute rheumatism may be a possible diagnosis, though the painlessness of the effusion is against this, some of the cases recorded as tuberculous rheumatism began with symptoms suggestive of subacute rheumatism. The general character of the attack is more like an intermittent hydrarthrosis, perhaps caused by some allergic process. The age of onset and the character of the joint symptoms are against rheumatoid arthritis, though such a diagnosis could not be entirely excluded. Treatment might reasonably be carried out on sanatorium lines, that is, by rest, fresh air, cautiously graduated heliotherapy, and tonic measures, but not in a sanatorium—a sea-bathing hospital would be more appropriate.

### Treatment with Vitamin B<sub>2</sub>

**Q**—I have had a case of scrotal eczema with pruritus ani. The eczema was cured and the pruritus controlled by vitamin B<sub>2</sub> (riboflavin 3 mg morning and night), but treatment causes nasal congestion. Can you explain this, suggest a remedy and say if it is dangerous to increase the dose?

**A**—It is very unlikely that scrotal eczema and pruritus ani would respond to treatment with riboflavin unless the condition is due to a gross vitamin-B-complex deficiency. In this case treatment with a vitamin-B-complex preparation such as yeast, liver, or 'marmite' is likely to be more effective than with any single vitamin. It is also very unlikely that the riboflavin causes nasal congestion. It is an extremely harmless substance, no side effects from its use have been reported, and no harm can come by increasing the dose—although this would appear to be unnecessary, since 6 mg a day, the dose given by the inquirer, is quite enough for the treatment of mild deficiency.

### Reversion of Changes caused by Androgens

**Q**—Are the changes brought about by the administration of androgens reversible? The case I have in mind is that of a young woman who was treated abroad with large doses of male hormone. She now has a pronounced enlargement of the clitoris and other signs of virilism. Can any treatment be suggested?

**A**—The changes are largely reversible, but the reversion may take several months. In the case of the clitoris and the larynx complete reversion to the condition existing before androgen therapy was begun does not necessarily occur. There is no hormone treatment likely to counteract the residual changes.

### Treatment of Varicose Veins after Sympathectomy

**Q**—A patient has developed a small varicose vein in the leg, which should be injected with some sclerosing agent. Is the fact that a sympathectomy was successfully performed five years ago for erythrocyanosis cruris puellarum a contra-indication to injection treatment? The circulation in the legs has been quite good since the operation.

**A**—There is no objection at all to the injection of the veins in erythrocyanosis cruris puellarum frigida whether sympathectomy has been done or not. Varicose veins are often associated with this condition, and their treatment helps it slightly.

### Ulceration of Mucous Membranes

**Q**—A mother of three children aged 42 has suffered continuously for 18 years from multiple small ulcers on the mucous membrane of the mouth, tongue and vagina. They started after her first confinement and became chronic after her second. Sometimes she has only two or three on one occasion she had 19. She once had haemorrhoids and the ulcers appeared on the extruded nuchous membrane. The Wassermann reaction is negative, test-meal examination revealed nothing abnormal and the blood and urine are normal. Ultra-violet radiation improved the vaginal ulcers but mouth-washes aggravated the mouth condition. Culture from the ulcers gave growth of staphylococci and streptococci which were only mildly sensitive to penicillin. What would you suggest for a cure?

**A**—Coincident ulceration of the mouth, vulva, vagina, and sometimes anus, though not very common, is a syndrome well known if only because its treatment is so unsatisfactory. The relation of ulceration to menstruation is not mentioned in the question, but very often it is striking, nor is it stated whether the ulceration cleared up during pregnancy, which it usually does. Many questions have been received on similar cases, and replies published in the *Journal* (March 15, 1947, p 365, June 15, 1946, p 940, Dec 25, 1943, p 839) should be consulted. The cause of the condition is unknown, although there are many theories to account for it. Simultaneous affection of the vulva and mouth is a feature of several diseases—e.g., glossitis and vulvitis in diabetes and in various anaemias, angular stomatitis and pruritus vulvae in anaemias, ariboflavinosis, and other deficiency states. The typical cyclical ulcerations may have an endocrine cause and a recent suggestion put forward by B Zondek and Y M Bromberg (*J Obstet Gynec Brit Emp* 1947, 54, 1) is that the condition is sometimes an allergic manifestation to one or other hormone. They give details of tests which can be applied. Previous writers have pointed out that there is sometimes a strong family history of various allergic states in these cases. The patient should be carefully investigated for evidence of dietetic deficiency, anaemia, and diabetes, and skin-sensitivity tests should be carried out. Any focus of infection in the mouth should be dealt with, as should any form of dyspepsia. If no obvious cause is found, empirical treatment with large doses of vitamins A, B, and C should be tried in turn. Chorionic gonadotrophin, 500 i.u. intramuscularly twice weekly, appears to help in some cases.

### Low-calorie Diet for Obesity

**Q**—Can you give details of a diet for obesity supplying 1 000 calories daily having regard to present-day difficulties of supply and to the patient's dislike of cooked green vegetables—e.g. cabbage, cauliflower, sprouts? The patient eats lettuce and other salad vegetables also peas, French beans, carrots, and beetroot.

**A**—The following diet will meet most of the requirements of the questioner. Difficulties arise when attempts are made to give the patient a sensation of satiety. This has usually been done by distending the stomach with green vegetables and fruit, which have a negligible calorie value. It is questionable whether this is the correct course, the fundamental aim in treating obesity is to educate the patient to control his appetite, and it is better that he should suffer for a few days the pangs of unassuaged hunger than to pander to his lust for repletion. The intense hunger disappears after a week and during this time it is perhaps justifiable to keep it in check with "benzedrine" thereafter a low-bulk diet can be taken without distress.

**Breakfast**—Raw fruit, no sugar, one boiled or poached egg, or grilled kidney, or smoked haddock, or steamed white fish, two thin slices of bread, toasted if desired, butter, jam, or marmalade very thinly spread, tea or coffee with milk to taste.

**Lunch**—Clear soup, lean meat chicken, rabbit, boiled white fish, lobster, crab, as much as desired, salad as much as desired, fruit raw or cooked without sugar, as much as desired.

**Tea**—Two thin slices of bread very thinly buttered, with tomato, cucumber, cress, or "marmite" as a sandwich filling, tea with milk to taste, no sugar.

**Dinner**—As for lunch.

A concentrate of vitamins A and D should be prescribed.

### Yellow-fever Immunization

**Q**—What is the most satisfactory method of yellow fever immunization? Is it now required that a second inoculation be given six months after the first with annual boosters thereafter?

**A**—This is not the usual ruling. Certificates of yellow-fever vaccination as were recognized by Unrra and generally accepted the world over are valid for four years. Individuals in the midst of an epidemic would probably be wise to be reinoculated after a shorter interval. The accepted vaccines are those made from chick embryos infected with the attenuated 17D strain, which is made in North and South America, England, and South Africa, and the mouse-brain vaccine made in Dakar from mice infected with the French neurotropic strain. A single injection of vaccine subcutaneously is given in either instance.

### Death Rate from Cancer

**Q**—As medical officer of health to a population of 8 900 in Scotland I should like to know if our 16 deaths from cancer is higher or lower than the rate for England and Wales?

**A**—The age constitution of the population at risk is an important factor in comparing death rates from cancer, since this disease is one of later life. If the age structure of the population was proportionately the same as in England and Wales then, on the basis of the mortality experience of England and Wales, the number of expected deaths would be 17.

### Use of Tap-water for Injections

**Q**—Are there any objections to using London tap-water in place of distilled water for the usual subcutaneous and intra muscular injections?

**A**—In an emergency, and when distilled water is not available, tap-water may be used for dissolving a tablet of, say, an alkaloid to be given by hypodermic injection. How far this practice should be extended depends on the nature of the medicament and the volume to be injected. London water is chlorinated and also contains various mineral constituents, mainly salts of calcium and magnesium, anything reacting with these substances should naturally not be made up in tap water. The injection of a considerable volume would be inadvisable, owing to the possible presence of pyrogens, these are more likely to be present if the water comes through a cistern which needs cleaning. The injection of any solution made from water which has not been autoclaved involves a very small risk of producing gas-gangrene owing to the chance presence of spores of *Clostridium welchii* or some related organism. For this reason alone the practice should be discountenanced.

### NOTES AND COMMENTS

**British Rheumatic Association**—Dr F. HERNAMAN-JOHNSON, Chairman of the Council of the British Rheumatic Association, writes: As you rightly say in your report (June 26, p 1249), the British Rheumatic Association is chiefly a lay body. It leaves matters of research strictly to the Empire Rheumatism Council, but it is directly interested in securing that treatment based on existing knowledge shall be readily available to all rheumatic sufferers. We would welcome a large number of general practitioner members. They could tell us the needs of their particular district and help to increase the membership of the association among their patients. A very large total membership is aimed at, perhaps 100,000, and this can be reached only by the co-operation of that part of the medical profession which comes into intimate contact with the people. The literature of the British Rheumatic Association will be sent to anyone who cares to write to 5, Tite Street, Chelsea, London, S W 1.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Almoloj*. *Westcent* London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1 on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Brimedads*. *Westcent* London. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the ASSOCIATION, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra*. *Westcent* London.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 21 1948

## COMPENSATION

### AN AGREED STATEMENT

Anxiety is being expressed by general practitioners who feel that a claim for compensation submitted in accordance with the regulations will not fairly represent the value of the goodwill of their practices on the appointed day. It is hoped that the following statement which has been agreed by the Ministry of Health will clear up misunderstandings.

It should be appreciated that in drafting regulations regard is had to the normal procedure which can be followed in the great majority of cases. However, to meet exceptional circumstances provision has been made to cover the anomalies which may arise. The case of the ex-Service practitioner who has not had time to re-establish his practice is only one of a number of anomalous cases which cannot be assessed on the mere statement of the income for the last two accounting years.

The situation will be met by reference to the Practices Compensation Committee, and the aim of the Minister, with the help of this committee, is to ensure a fair distribution within the global sum. Cases which are not quite straightforward will be referred to the Committee under Regulation 9, and the Committee is given power to fix what they consider to be a fair assessment. The relevant provision in Regulation 7 (2) (ii) is as follows:

"in the case of any claim referred to the Committee the Committee shall fix as the annual loss in respect of the practice such sum as they estimate fairly to represent the average gross yearly receipts of the practice."

Any practitioner who is desirous of bringing forward any circumstances which he wishes to be taken into account in fixing the annual value of his practice should submit with his application full details of those circumstances together with such supporting evidence as he deems appropriate. He should be prepared to supply any further facts at the request of the Practices Compensation Committee and he is reminded that if he feels aggrieved by the decision of the Committee he may appeal to arbitration.

### Forms for Obtaining Certificates

Doctors claiming compensation who have not already applied to an Inspector of Taxes for a certificate for the purpose of Regulation 7(3) of the National Health Medical Practices (Compensation) Regulations, 1948, should apply for the appropriate form on which to obtain such a certificate to the Secretary, Ministry of Health (A G D 3), Whitehall, SW 1.

## PRESCRIBING IN N.H.S.

*In reference to the letter under the above heading from Dr M. Lichtenstein in the Supplement of Aug 14 (p. 84) the following extract from Department of Health Circular E.C.S. 27/1948 to executive councils in Scotland may be of interest:*

Supply by practitioners of drugs and appliances required in special circumstances. Apart from the cases of persons in rural areas to whom practitioners may be required by the executive council to supply all necessary drugs and appliances practitioners are required to supply to their patients such drugs and appliances as are required (a) for immediate administration or application or (b) for use before a supply can be obtained by means of the issue of a prescription and they may also

(c) supply any other drugs which are administered by them in person. It has been agreed with the British Medical Association that the arrangements under which practitioners may obtain and keep in stock supplies of drugs and appliances of the classes referred to will be similar to those which have been in operation under National Health Insurance—i.e., the practitioner will order his requirements from a local chemist and the latter will be paid for the articles supplied at Drug Tariff rates. There will, however, be two changes from the National Health Insurance arrangements:

1 There will be no fixed lists of "Emergency Drugs and Appliances" to which practitioners will be restricted; they will be free to order for "stock" whatever they require so long as they confine themselves to such articles as are required for the three purposes already stated.

2 A special order form (Form E.C. 10A) will be supplied for the convenience of practitioners, who will not, as hitherto, use the ordinary prescription form for the purpose of ordering stocks of drugs, etc. (Copies of these forms are being printed and will be supplied very shortly to executive councils for issue to practitioners.)

## WHITLEY COUNCIL FOR NURSES AND MIDWIVES

The Whitley Council will determine salaries and general conditions for nurses and midwives in England and Wales and Scotland under the National Health Service. It consists of a staff side and a management side, and the chairman will be appointed from each side alternately every year. Formerly the Rushcliffe Committee advised the Minister of Health on salaries and conditions for nurses and midwives, while in Scotland the Secretary of State was advised by the Guthrie Committee. Both these committees have now been wound up.

### Representatives of the Management Side

*Association of Education Committees* Alderman W. C. Redman

*Association of Municipal Corporations* Councillor Professor F. E. Ty'ecote

*County Councils Association* Mr T. O. Steventon and Alderman E. A. Cross

*London County Council* Representatives not yet nominated  
*Scottish Local Authorities* Councillor A. T. Morrison and another not yet nominated

*Regional Hospital Boards* Miss Mary Jones, Mr H. Goddard, and Mr James Wyatt

*Regional Hospital Boards Scotland* Miss Bella Jobson

*Department of Health Scotland* Mr E. W. Hancock and Mr J. Cochrane

*Ministry of Health* Miss E. Cockayne, Mr W. O. Chatterton, Mr E. M. T. Firth, Mr S. W. Mayne, Miss E. M. R. Russell-Smith, and Mr H. Old (Welsh Board of Health)

### Representatives of the Staff Side

*Association of Hospital Matrons* Miss H. Dey and Miss I. R. Taylor

*Association of Supervisors of Midwives* Miss M. E. Platt  
*Confederation of Health Service Employees* Mr R. Barker, Mr C. Bartlett, Mr C. F. Comer, and Mr J. T. Waite

*National Association of Administrators of Local Government Establishments* Mr R W Ramsey

*National Association of Local Government Officers* Mr Haden Corser, Mr G W Phillips, Mr C A W Roberts, and Mr W Pitt-Steele

*National Union of General and Municipal Workers* Mr C H Beckett Mr A Bowden, and Mr D Horan

*National Union of Public Employees* Mr S Hill, Mr W L Griffiths, Mr S Barton, and Mr D Davies

*Royal College of Midwives* Mrs Alan Baker, Miss N B Deane, Miss J Ferlie, Miss F Gore, Mrs F R Mitchell, and Miss V Shand

*Royal College of Nursing* Miss F G Goodall, Miss M Houghton, Miss W Holland, Mrs E O Jackson, Miss M Johnston, Miss J E Laycock, Miss M Macnaughton, Mr J Sayer, Miss B Shenton, Miss M D Stewart, Miss B Wood and Mrs A A Woodman

*Scottish Health Visitors Association* Miss C Keachie

*Scottish Matrons Association* Miss E G Manners

*Women Public Health Officers Association* Miss M Blanchard and Miss N K Ross

## National Health Service News

### Certificates for Persons Attending Hospitals

When a patient is attending hospital and is not, for the time being, consulting his own doctor, it should not be necessary for him to be referred back to his doctor for a medical certificate. Stocks of official forms have been issued to all hospitals, and instructions on their use have been sent to hospital management committees and boards of governors. If a doctor finds that patients referred to a particular hospital are being sent back to him for certificates of incapacity, it is suggested that the matter be taken up with the hospital direct or with the local executive council.

### Persons Charged with Drunkenness

What is the position of a doctor who is called to a police station by a person charged with drunkenness? The view of the Ministry of Health is that if such a person exercises his right to call in his own doctor, and the doctor responds to the request, the doctor is entitled to charge the person a fee for his attendance, even though the person may be on the doctor's list under the National Health Service Act. This view relates solely to cases in which the person is charged with drunkenness and no medical treatment is required or given.

### Merchant Seamen and the NHS

Foreign-going British seamen whose names were already on the list of an insurance doctor should take no action if they wish to remain on that doctor's list, but others may complete Form EC 1. As they have not a national registration identity number, they should quote the number of their seamen's registration card or of their discharge book. Visiting seamen not domiciled in Britain are entitled to services under the NHS Act while ashore in this country and should obtain treatment as temporary residents.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley

## Correspondence

### War Service of Specialists

SIR—In the Spens report on the remuneration of specialists and consultants, and in the pamphlet on pensions recently distributed, no mention has been made of the position with regard to war service. Does such service count towards seniority and towards pension?

Those specialists, particularly in full-time medicine, who for one reason or another were unable to be released from their civil hospitals during hostilities, have acquired much seniority as regards their posts, with consequent increases in basic salary under the NHS, and in their pensions.

Some, under existing rules, are being granted a variable number of years' seniority added to their pensions on the count of their past experience with the county service and their future value to the State. It seems quite fair, and indeed only proper, under such circumstances, that ex-Service doctors, both clinical and administrative, should count in full their years of service when their basic salary and their pensions are assessed.

As regards pension, it may be argued that while in the Service they received exactly the same salary and gratuity as regulars, which is worked out on a pensionable basis, and that therefore such service should rightly be regarded as contributed service. As regards experience, many of the officers concerned have acquired considerably greater and wider experience and have accepted heavier responsibilities than those in civil hospitals and full due should be given to this when salary scales are adjusted—I am, etc,

Ashford Middles\*

C A HINDS HOWELL

### Head-hunters

SIR—In his letter on "Reduced Incomes" (*Supplement* July 17 p 48) Dr C J Gordon Taylor makes a true but very sad statement that the only way to make a living is to taken on patients by the thousand. The Minister pays according to the number of heads on the doctor's list. In other words, we must become head-hunters.

Those GPs who have always set themselves a high standard in their everyday work and have taken pride in doing the best for their patients will thus find their incomes reduced. The alternative is to debase these standards, take on large numbers, and do what they know to be poor work under sweated labour conditions. These sweated-labour conditions turn out in actuality to be a test of physical endurance. They make no allowance for the not-so-young doctor, nor for those of exceptional experience and capability. The future is indeed grim, except for the head-hunters. The complacent pomposity of the BMA in saying doctors must make the Service a success is infuriating, because the better the doctors do their work the worse their pay.

Then there is the unfairness over the "free" supply of drugs, etc., to private patients—and some people still prefer to remain private patients, just as some people prefer to send their children to schools of their own choice. Day after day in the Press appeared a notice issued by the Ministry of Health about the Service: "You can use any part of it, or all of it as you wish."

Was this statement a careless inaccuracy, a deliberate falsehood, or just one example of the Minister's "burning hatred" (his own words) for those many people lower than vermin? Whatever the answer, it is obviously unjust that drugs should have to be paid for. Will the BMA insist that the Minister should stand by his printed word that "you can use any part" of the Service?—I am, etc,

Birmingham

HUMPHREY FOXELL

### Medical Records

SIR—I was pleased to see Dr C Coley Grayson's suggestion (*Supplement* July 24, p 60) that the back of the medical record envelopes should be left blank for the notation of salient points. I should like to make a suggestion which would, in my opinion, materially improve the front of the MREs. This is, that a small column should be provided behind the patient's address and subsequent addresses for his or her telephone number. This would often be helpful for communication in maternity

cases, to give information regarding urgent admission to hospital, important laboratory reports, etc

The layout of the new continuation cards is, I think, less satisfactory than that of the old NHI cards in the following respects (1) By reducing three columns to one (for A,V,C) it is made much more difficult to review a case and see at a glance when a patient had a certificate or was signed off, when he was visited or had only a prescription repeated ("M" or B)—dates which are essential in compiling reports at a later date (e.g., for the Ministry of Pensions insurance companies, etc.) (2) The column reserved for diagnosis was of definite value. It permitted the instant review of the patient's medical history and was a salutary reminder to unmethodical workers that other doctors at a later date might have to study the case history. (3) It is in question whether a doctor should spend his time discovering the national registration identity number of a new patient. Surely it is more to the point to state at the head of the continuation cards the year (or in infants the date) of birth and occupation of the patient in two words.

At the present time, when we are spending more and more of our time in clerical work, everything possible should be done to confine it to essentials—I am, etc.,

London NW 9

J PULFER

PS—I am enclosing one MRE and a new and old form, EC 7

### Domiciliary Maternity Service

SIR—Surely Dr T G Scott (*Supplement* July 24, p 59) is incorrect in some of his interpretations of the domiciliary maternity service. The Minister has stated in the letter (*Supplement*, June 5, p 155) from Sir William Douglas to Dr Hill of May 26 that "the main objective—of encouraging the development within general practice of groups of practitioners with rather more than normal aptitude for midwifery—could still be achieved if he introduced a public payment of £5 5s for all doctors and £7 7s for those on the special list." Those on the latter "will go on, no doubt, with a view of regular and frequent midwifery work—and it will no doubt be these with whom the local midwifery authorities will wish to make arrangements to be 'on call' to midwives under the Midwifery Acts." Whatever we may think of the Minister and his methods, to describe £7 7s doctors as safe and £5 5s doctors as unsafe is not fair comment and not reassuring to prospective patients.

Regarding attendance at confinements is it not accepted that one of the important factors in a satisfactory labour is the attitude of mind in which a woman anticipates her confinement? If it appears clear that psychologically the attendance of the doctor will help her, then surely he or she will deem this necessary.

Dr Scott rightly stresses the necessity for antenatal examinations and domiciliary confinements to be carried out by competent midwives, and then writes, "This in fact means the district nurse" thereby, in my opinion, casting an unwarranted slur on a very fine body of extremely hard-working and conscientious women—I am, etc.,

Poltimore D von

R FORTESCUE-FOULKES

### Amendments Required

SIR—Already the working of the National Health Service Act and its regulations has made evident the urgent need for reform of some of its provisions. I venture to suggest that the profession should draw up a list of amendments which are required and append a 10-point programme.

1 The maximum number of patients which one doctor may accept on his list should be reduced and the capitation fee correspondingly raised. Overhead expenses are proportionately greater the lower the "income." No doctor should be faced with the dilemma of either accepting so many patients that he cannot look after them, or so few that he cannot live.

2 Pharmaceutical benefit should be made immediately available to private patients.

3 Ante- and post natal benefit should still be available for maternity patients who make private arrangements in advance for the attendance of their doctor at the time of delivery whether necessary or unnecessary.

4 National Health Service patients who are normally entitled to free maintenance in a hospital should not forfeit this benefit if they go into a paying bed. They should pay only for the extra amenity.

5 No practitioner should be compelled to dispense for National Health Service patients nor should he have to take any responsibility for making arrangements for the provision of dispensing facilities.

6 National Health Service prescriptions, in suitable cases, should be made "repeatable" without further consultation with the doctor.

7 *Certificates* (a) A number of categories should be issued only at extra charge to the patient. (b) Disablement initial certificates should be issuable for longer periods in cases in which it is clear that disablement will persist for several weeks. (c) Permanent disablement certificates should be issuable in cases of permanent disability—e.g., total blindness. (d) Milk certificates category (2) should be issuable for longer periods. (e) The unit of milk issue should be a 1/2 pint. Category 1 would normally get 4 units, and category 2 would normally get 2 units, but variation of unit number could take place within the category at the discretion of the doctor.

8 Mileage claims should be simplified and the amount raised to 1s per mile (cost per mile when depreciation and all other expenses are included).

9 In the absence of equipped health centres the State should take financial responsibility for the provision of necessary equipment—e.g., record card cabinets.

10 Provision should be made on medical cards for transfer of patients.

—I am etc

Winchester

C J PENNY

### The Unattended Telephone

SIR—In a recent issue (*Supplement* July 3, p 28) you again suggest that the profession are very slow to take up the automatic telephone. You say the cost is approximately £80. You fail to mention £25 installation charge and £25 per annum maintenance. I am very keen to have the instrument, but 10s a week maintenance is expensive and very much implies that the machine will give trouble—I am, etc.,

Emsworth Hants

H B C SANDIFORD

### Trade Union

SIR—Whatever our feelings as individuals may be about the new Health Service, one fact stands out and that is that we are now employed persons depending on the Government for our pay and terms of service, and we should have a trade union in order to ensure that in future we obtain fair terms by collective bargaining. I hope that no silly squeamishness will prevent our taking this necessary step—I am, etc.,

Salisbury

PAUL HARRIS

### Children's Medicines in the National Formulary

SIR—The National Health Service has now been in operation for one month, and my personal impression as a principal in a busy industrial practice is on the whole favourable. However, there is an important criticism I should like to make.

Children of the present generation are accustomed to be given by their doctor palatable medicines. The children's medicines in the National Formulary are strongly reminiscent of the nauseous compounds with which my childhood's palate and stomach were insulted. This is a retrograde step and a grave psychological blunder. In my opinion it is urgently necessary that an interim list of children's prescriptions should be issued for the National Formulary, and for this the wholesale manufacturing chemists should be taken into consultation and an agreed list of palatable concentrated mixtures drawn up which would merely require the addition of that important ingredient, Aq fontis to dilute them to the required strength. It is important that these various mixtures as made by different firms should be identical in appearance and taste and should be "elegant preparations." At present many of the children object strongly to NF prescriptions.

One well-known firm puts up a "suspension sulphathiazols," which is very palatable and contains four grammes to the ounce—i.e. one drachm equals half a tablet. I have used it for some months past and always order it for my little panel patients, as I find they so often spit out the tablets. I should like to see equally palatable suspensions of the other "sulpha" drugs for administering to children.

The use of palatable formulae for children would not cost the country any more, as they would be manufactured on a large scale and would save an immense amount of the chemists' time. According to present regulations the NF prescriptions must be compounded afresh for each prescription. The matter is very urgent, as autumn and winter are fast approaching—I am, etc.,

## THE REDUCTION IN DENTAL CARIES IN 5-YEAR-OLD LONDON SCHOOL-CHILDREN (1929-47)

BY

MAY MELLANBY

AND

HELEN MELLANBY, Ph D, M.B, Ch B

(Nutrition Building National Institute for Medical Research, Mill Hill London)

The present paper is a continuation of a series describing the dental condition of 5-year-old London County Council school-children in 1929, 1943, and 1945 (Mellanby and Coumoulos, 1944, 1946). Between July and the end of October, 1947, 1,590 such children were examined with the object of finding whether the improvement observed in 1943 and 1945 had been maintained. The children lived in the same areas of London, and in the majority of cases attended the same schools as those used for the earlier surveys. A few of the schools previously visited were no longer available, substitutes in the same localities were then provided by the London County Council. As before, only children who had attained their fifth birthday but had not yet reached their sixth were selected, the average age being the same as in the other surveys. Although the presence of any permanent teeth erupting or erupted was recorded, this report refers only to the deciduous dentition.

In this 1947 survey the methods and standards adopted were similar to those used previously, full details of which can be found in the earlier papers.

### Methods

**Structure**—The structure of the individual teeth of each child was assessed according to the method devised and first used by M. Mellanby as early as 1923 and since then also employed on numerous occasions by others, including King, Coumoulos, Deverall, H. Mellanby, and Davies.

In essence the method consists in rubbing the labial surface of each tooth with a fine probe of standard size and sharpness (S.S. White Stainless No. 37). After some practice it is possible to grade teeth in the mouth by the smoothness or roughness felt with the probe. It was shown many years ago that this external enamel texture could be correlated with good and poor microscopic structure (M. Mellanby, 1934). On sectioning smooth teeth showed what were judged to be well-calcified enamel and dentine, whereas external roughness was usually associated with a less well-calcified minute structure, in particular with dentine containing interglobular spaces. The various macroscopic grades of surface roughness or defect are referred to as M-Hypoplasia (M-Hy) to distinguish them from gross or "textbook" hypoplasia (G-Hy), which is the only type whose existence is commonly recognized by dentists. Gross hypoplasia, the aetiology of which is not fully understood, is uncommon in deciduous teeth in this country; it is readily visible to the naked eye, the teeth so classed having obvious enamel pits or in some instances areas from which the enamel is lacking.

In surveys of this kind there are always some teeth whose structure it is difficult or even impossible to grade. This situation

may arise, for instance, when a tooth has some structural defect which does not correspond to any of the grades described below. These teeth are included in Tables under the heading "Hy unclassified". A small proportion of teeth were so carious and others had such heavy deposits of tartar over certain areas that no opinion could be formed about their original surface structure. Where for either reason it was impossible to make a satisfactory estimate of the average structure the teeth are recorded as being present in the mouth but are not included in the structure tables.

By the probe method described, each tooth whose structure could be assessed was graded according to the following symbols:

Hy, No hypoplasia, smooth shiny surface—good structure

M-Hy, Slightly rough surface—slightly defective tooth

M-Hy, Rougher surface—definitely defective

M-Hy, Very rough—very defective

G-Hy All varieties of gross or "textbook" hypoplasia

**Caries**—Each tooth was examined for caries with a standard probe (S.S. White Stainless No. 12) and illuminated mirror.

Any decay that could be diagnosed by this method was graded as 1, 2, or 3. Grade 1 included very early and suspected fissure and approximal caries and cavities up to the size of a pin-hole, grade 2 included all cavities from pin-hole size up to one-quarter of the crown, and grade 3 contained those teeth with more than one-quarter of the crown decayed, including those of which only the roots were left, and all missing canines and molars, which were assumed to have been extracted on account of caries. Obvious undermining decay was taken into account in judging the size of a cavity. Any incisors not present were counted as naturally shed.

A child's dentition was regarded as caries-free only when no caries, active or arrested, was recorded on the chart. A mouth containing one, two, or three teeth which were included in grade 1 caries, but none in the other grades, was described as being "almost caries-free". This system of classification was adopted in order to obtain figures which could be compared with those obtained in the 1929 survey, when so few children were completely caries-free, according to the above standards, that the two groups "caries-free" and "almost caries-free" were combined, even so the total was then only 4.7%.

**Other Conditions**—Besides structure and caries, a number of other conditions were noted for each mouth. These included the arrest of the carious process, treatment of caries, mottling of enamel, the state of the mouth, spacing of the teeth, obvious tartar, gingivitis, occlusion, attrition, and the presence or absence of stain, but not all these conditions are considered in this report.

## General Results

Before the detailed analysis of the data obtained in the latest survey is considered in relation to that of the earlier investigations a brief general comparison may be made

TABLE I—Percentages of Caries-free Children

Year	Total No of Children Examined	% Caries free	% Almost Caries free	Total %
1929	1 293	—	—	4.7*
1943	1 870	14.9	9.3	24.2
1945	691	24.2	3.9	28.1
1947	1 590	28.1	9.4	37.5

\* Percentages of caries free and almost caries free children not separately estimated in 1929

The number of children whose dentitions were of good structure showed obvious improvement from survey to survey, and the upward trend observed in 1943 and 1945 in the proportion of children who, according to the probe and mirror method, could be described as caries-free or nearly so continued in 1947 (see Table I and Graph). It was found that, whereas only 4.7% of the children examined in 1929 could be so classed, the figure had risen in 1943 to 24.2%, in 1945 to 28.1%, and in 1947 to 37.5%.

Showing increase in percentage of caries free and almost caries free children 1929 to 1947

The percentage of teeth present in the children's mouths at the time of the 1947 survey, differed only slightly from the percentages found at the earlier inspections. The respective figures for 1943, 1945, and 1947 were 92.2, 94.4, and 93.9%.

## Detailed Results, 1943-7\*

**Structure**—Table II, which compares the results of the three surveys, shows the percentages of teeth included in the different grades of structure and also gives a computation of the extent of defective structure expressed as the average hypoplasia figure (AHF). The AHF is arrived at by allotting a number to each grade of M-hypoplasia (1 for M-Hy<sub>1</sub>, 2 for M-Hy<sub>2</sub>, and 3 for M-Hy<sub>3</sub>) and dividing the

\*The detailed 1929 results do not appear in these tables, as they were not published and the charts were lost early in the war

\*AHF (average hypoplasia figure) =

$$\frac{\text{Total hypoplasia figure}}{\text{Total No of teeth examined for structure (excluding those with gross or unclassified hypoplasia)}}$$

total hypoplasia figure so obtained for any group of teeth by the total number of teeth in the group, excluding those showing gross hypoplasia. Thus the greater the number of teeth classed as of good structure (Hy<sub>0</sub>) or included in the less severe grades of M-hypoplasia, the lower the AHF.

As is seen from the average hypoplasia figures (AHF), there was an improvement in structure in each type of tooth from 1943 to 1945 and from 1945 to 1947. The actual reduction in the AHF in the latest survey as compared with the previous one was greatest in the upper centrals and lower first and second molars, but the percentage reduction was substantial in *all* the lower teeth, as in the upper centrals. The least change in percentage reduction of the AHF in 1947 as compared with 1945 occurred in the upper molars, but these teeth are often covered by a thin film of tartar and it appears to us possible that their hypoplasia figures may be less reliable than those for other types of teeth.

Turning to the proportion of teeth showing the various grades of structure, it is seen that 47.1% were of good structure (Hy<sub>0</sub>) in 1947, as compared with 38.0% in 1945 and 30.7% in 1943. The progressive improvement from survey to survey was distributed among all types of teeth except the upper molars, which showed little change in structure in all three surveys. A possible reason for this will be considered in a future paper. In 1947 both the first and second lower molars were much better than in 1945. This was particularly evident in the case of the second molars, whose improvement in this period was approximately 179% (i.e., from 7.5 to 20.9%). As in the previous surveys, the upper teeth of all types were on the average of poorer structure than their counterparts in the lower jaw. The incidence of gross hypoplasia was lower in 1947 than formerly, whether the teeth were considered *en masse* or in individual types.

**Caries**—As has been already stated, the amount of caries in the 5-year-old L.C.C. school-children underwent a considerable reduction in 1947 as compared with 1945 and 1943. Table III shows the incidence and extent of caries in each type of tooth and in all types together for the three surveys. Like the structure of the teeth their condition as regards caries is expressed in two ways—first as percentages of teeth included in the various grades, and, secondly, as the average caries figure (ACF). For the latter the same principle is adopted as for the AHF. The number 1, 2, or 3 is allotted to each carious tooth according to the severity of the disease, and the total caries figure is divided by the number of teeth in the group concerned. The smaller the ACF the less the degree of caries in the group as a whole. The table indicates that there was improvement at each successive inspection in all types except the lower central incisors,

NOTE—This table does not include the few teeth shown under the heading "Hy Unclassified" in Table II

where both incidence and extent of caries remained the same in 1947 and 1945. Here so few teeth were carious even in 1943 that little improvement could be expected. The proportion of caries-free teeth of all types increased from 69.9% in 1943 to 73.5% in 1945 and 79.7% in 1947. In the latest survey the most striking increase in this respect was in the upper and lower second molars, where there was most scope for improvement. It is of interest to note that although in 1947 over 70% of the children examined had at least some caries, yet the disease occurred in only about 20% of the teeth, including fillings and extractions. The proportion of carious teeth had diminished by approximately 33% since 1943.

**Relation between Structure and Caries**—All previous surveys using M-hypoplasia standards for structure showed that the better-formed teeth were less liable to decay. This was also true of the 1947 survey, as can be seen by reference to Table IV. For example, the incisors with no hypoplasia had a caries incidence of 2.4%, whereas those with grades M-Hy, and M-Hy had a caries incidence of 16.7 and 36.8%, respectively. Of the very few incisors in the M-Hy, grade 51.5% were carious. The corresponding figures for

molars with no hypoplasia and with M-HY, and M-Hy, were 11.9%, 30.7%, and 43.4%. As in the case of the incisors, there were relatively few molars in the M-Hy, grade, but 60.4% of them were carious.

**Other Conditions**—There was less arrest or "spontaneous healing" of decay in individual teeth in 1947 than in 1945, though more than in 1943 (see Table V). The reason for this is not clear. The amount of treatment of carious teeth (see Table VI), which was lower in 1945 than in 1943, had risen in 1947 nearly to the 1943 level, and the percentage of extractions was almost identical in these two surveys.

Reference has previously been made (Pickerill, 1923, Ayers, 1939, Pincus, 1941, Pederson, 1946, Mellanby and Coumoulos, 1946) to the superficial stains commonly seen on children's deciduous teeth, and to the fact that mouths in which black and dark-brown stains occur appear to be associated with a lower incidence of caries, and green stains with a higher incidence. In the 1947 survey this was again the case (see Table VII).

## Discussion

An account has been given of a further survey, made in 1947, of the dental condition of 5-year-old children attending London County Council schools. Comparison has been made between the results of this work and those obtained in the examination of children of the same age group attending the same or neighbouring schools in 1929, 1943, and 1945. The main findings as regards the incidence of

TABLE V—Teeth showing Arrest ( Spontaneous Healing ) of the Carious Process

caries *per child* observed over this period of 18 years, are set out in Table I and the Graph. It will be seen that the improvement has been great, especially between 1945 and 1947. In the first period of 14 years the average increase in the percentage of caries-free or nearly caries-free children was at the rate of 1.4% per year, in the second period of approximately two years it was 1.95%, and in the third period, also of about two years, it was 4.7%. Tables II and III indicate that the structure of the teeth also has greatly improved from 1943 to 1947 and that the incidence and extent of caries *per tooth* have been substantially reduced.

These surveys were preceded by experimental investigations on animals, begun in 1917, and by controlled studies on children which were the natural outcome of the animal work. The earlier experiments were devoted to a study of the food factors which affected the structure of the teeth, and ultimately it became possible to state the chief dietetic conditions favouring good and poor structure. For the former it was essential that the diet during the period of tooth development should be rich in available calcium and phosphorus and in vitamins D and A. Indeed, it was this work, in association with the researches of E. Mellanby on the subject of rickets, which first helped to prove the existence of a calcifying vitamin (vitamin D). The factors resulting in defective structure were mainly associated with both the quantity and the type of cereals consumed when vitamin D and calcium were deficient in the diet.

The clinical investigations on children showed the importance of the animal experiments in demonstrating the factors controlling dental structure, for these human studies pointed to the conclusion that, other things being equal, well-calcified teeth, according to the criteria used, were less liable to caries than badly calcified teeth.

Another fact of importance made clear by the animal experiments was that those diets which produced teeth of good and poor structure, respectively, also increased or decreased the resistance of teeth to a stimulus such as attrition, quite apart from their original structure. Thus teeth of either good or poor structure, when worn by friction, produced well-formed secondary dentine when the diet was of a highly calcifying nature, but produced badly calcified secondary dentine or none when the diet was deficient in calcifying properties.

Examination of children's teeth which had been subject to attrition indicated the same kind of reaction to this stimulus. A matter of greater importance, however, as was shown by investigations in Sheffield and Birmingham, was that a diet of high calcifying properties given after eruption of the teeth, whatever their structure, could prevent or retard the onset of caries, or, if the disease had already developed, bring about the deposition of well-calcified secondary dentine and ultimately the arrest of the carious process (Mellanby, 1934).

This effect of the post-eruptive diet in altering the resistance of teeth to caries, as opposed to the control of their development and structure by the diet before eruption, was substantiated by surveys made in 1945 on three groups of 5-year-old children, one group attending private schools, another attending London County Council schools, and the third comprising mainly destitute or illegitimate children living from an early age in public institutions and in most cases attending the institutional schools (Counmoulos and Mellanby, 1947). As a group, the institutional children had worse-formed teeth than the LCC or private-school children, but nevertheless had relatively less caries. On the basis of previous experimental and clinical evidence and of the conditions under which the children were reared it seemed fair to postulate that the pre-eruptive diets of the private school children were better in calcifying properties

than those of the children who became the responsibility of the institutions, and thus their teeth were of better structure, but on the other hand it appeared that the post-eruptive diets of the institutional children, who received regularly a diet rich in calcifying properties which included cod-liver oil, were on the average better in this respect than those of the private-school group, so that, in spite of the poorer structure, the teeth became more resistant to invasion and allowed less caries to develop.

Thus all these studies emphasize the importance of feeding children, first via the mother and later independently, on diets which will result in better calcification and greater resistance of the teeth.

It might be asked, then, whether there is evidence that the rapid improvement in the dental condition of the London County Council school-children, as regards both structure and freedom from caries, between the years 1943 and 1947, and especially between 1945 and 1947, as compared with the period 1929 to 1943, is due to causes indicated by the earlier experimental and clinical investigations. Certainly on the basis of that work such improvement would be expected to result from the series of changes in the dietary of this country during the war years. It was well known to those familiar with the subject that one of the main defects of the pre-war British dietary was its poor calcifying qualities.

Early in the hostilities, when restrictions in both quantity and quality of food necessitated the best possible use of available supplies, one of the first steps taken by the Government, on the advice of nutritional scientists, was to direct foods with high calcifying properties to those classes needing them most—namely, expectant and nursing mothers and infants. For example, from July, 1940, all expectant mothers could claim a milk priority of 1 pint (568 ml) a day. After the child was born two pints (1.14 litres) a day were allotted between mother and child for the first year, so that if the mother fed the baby herself then the two pints were available for her own consumption. From the age of 1 to 5 years the child's own allocation was 1 pint a day. This was reduced to half a pint (284 ml) for home consumption when school age was reached, but could be supplemented by 1/3 or 2/3 pint (190 or 380 ml) daily at school. In December, 1941, cod-liver oil was made available at a reduced rate through welfare centres, clinics, and food offices to children aged 6 months to 2 years, and in February, 1942, provision was extended to all children up to the age of 5 years. Expectant mothers were eligible for the oil from these official sources from December, 1942, and in April, 1943, vitamin A and D tablets were instituted as an alternative. At this time the vitamin D content of the Ministry of Health's cod-liver oil compound was raised from 100 to 200 international units per gramme, and has remained at this level. More eggs have also been available to mothers and young children than to non-priority classes.

Besides these special allocations there have also been, during and since the war years, a series of nutritional changes which have affected the whole population of the country, including, of course, the mothers and growing children. In this case also the calcifying as well as certain other qualities of the diet have been improved. For instance, since 1940 all margarine has had to contain vitamins D and A. In July, 1940, the vitamin D content was at the rate of 30 international units per ounce (approx. 1.1 u per gramme), in November, 1941, it was raised to 60 i.u. (2.1 u per gramme) and in January, 1945, to 90 i.u. per ounce (3.1 u per gramme), the vitamin A content has been from 450–550 i.u. per ounce (16–20 i.u. per gramme) throughout this period. With a weekly ration of 3 to 4 oz (85–113 g) of margarine for the average person,

It has been possible for each to receive between 12 and 50 i.u. of vitamin D and 200 to 300 i.u. of vitamin A per day from this source alone. Again, from 1942 onwards calcium has been added to all flour, at first the rate was 7 oz (200 g) of calcium carbonate per sack of 280 lb (127 kg), later in 1946 the amount was doubled. This addition of calcium was necessary because the raising of the extraction rate of the flour from the pre-war level of 70-73% to the wartime level of 85%, or even higher, greatly increased the phytate content of the flour, and phytate is known to decrease the availability of calcium in the food. This additional calcium was also an important adjunct to the dietary of non-priority people because of the limited amounts of milk, eggs, and cheese available. The larger amount of added calcium was sufficient to neutralize the harmful anticalcifying properties of the phytate, and any excess was available to help in promoting or maintaining the calcification of bones and teeth and for other physiological functions which required optimal calcium supplies.

Prior to the war many mothers had neither the desire nor the means to procure for themselves or their children adequate supplies of such foods as milk, eggs, and cod-liver oil. Recently, however, there has been an increasing awareness, on the part of both the medical and the lay population, of the nutritional benefits conferred by these foods, and generally speaking, money has not been a limiting factor, since Government subsidies have brought them within the reach of most families. If, however, people cannot afford to buy milk even at the subsidized rate, it may be obtained free of charge for expectant mothers and children under 5 years of age, and cod-liver oil, which was previously supplied at reduced rates, can to-day be had without cost under the welfare service.

It appears, then, from the foregoing account of recent diet changes, that an important reason for the more rapid improvement in the dental condition of children between 1945 and 1947 as compared with the preceding years is clear-cut. For the first time in the course of these surveys all the expectant and nursing mothers and all the children up to the age of 5 years have been in a position to obtain increased quantities of calcium and vitamin D via established milk, cod-liver oil, and egg priorities, and they have benefited further by other Government measures outlined above, so that throughout the whole antenatal and post-natal life of the latest group of children examined, who were born between November, 1941, and October, 1942, the diet available has been of consistently better calcifying qualities than that of the subjects of the earlier surveys. The pre-eruptive diet has produced better-calcified teeth than were formerly observed, and the post-eruptive diet has tended still further to increase the already higher resistance of these teeth to caries.

It must not be forgotten, however, that even to-day the majority of children in the young age group studied have some carious teeth and it seems most likely, on the basis of the present hypothesis, that this is due, in part at least, to the fact that many mothers do not avail themselves of all the special foods at their disposal. In order, therefore, to get some idea of what proportion of the mothers whose children were examined in 1947 actually took up their special allowances, a point was made of asking any who were present at the examination some simple questions on the subject. The numbers involved are too small to be of significance but they give an indication of the general trend.

Of the 224 women questioned 68% stated that they drank their prior milk and 65% of the children were said to have consumed a pint of milk a day during the pre-school period. In answer to the question "At what age did you begin to give your child cod-liver oil?" 20% of the mothers said that it was

given from the age of 8 weeks or less, but the amount and the length of time for which it was given varied. It was estimated that about 14% of the children had not had any cod-liver oil or alternative vitamin concentrate at any time, while the remaining 56% had had one or other of these supplements for some period during the first five years of life.

These figures suggest that there is still need for greatly increasing the numbers of women and children making use of the food priorities mentioned. This, of course, does not mean that the problem of caries would thus be solved. Indeed, it probably cannot be solved while the actual factors directly initiating the condition remain obscure, but when these are brought to light it may be possible to control the disease more directly and efficiently. Meanwhile the evidence grows stronger from year to year that the best way at present available to make a primary attack on this great health evil is to feed pregnant and nursing women, infants, and children along the lines which are known to produce well-constructed teeth and jaws and to increase resistance to decay—in other words, to ensure that both pre-eruptive and post-eruptive diets are relatively rich and balanced in available calcium and phosphorus and in vitamin D.

### Summary

The dental condition of 5-year-old children attending London County Council schools in 1947 has been described and compared with that of similar groups examined in 1929, 1943, and 1945.

The progressive improvement found in the two previous surveys has also been observed in 1947. The rate of increase in the percentage of caries-free or almost caries-free children between 1945 and 1947 has been more rapid than between 1943 and 1945, and certainly much more rapid than between 1929 and 1943. The same trend has occurred between 1943 and 1947 in the structure of the individual teeth and the incidence and extent of caries, the improvement being greater in the second two years than in the first two.

As in the 1943 and 1945 surveys, it is again suggested that the improvement is due to the increased calcifying properties of the dietary of this country, and particularly that of pregnant and nursing women, infants, and young children. The marked improvement in 1947 is thought to be mainly due to the fact that for the first time in these surveys the diet has been of consistently better calcifying qualities over the whole antenatal and post-natal life of the children concerned.

We wish to express our thanks to the London County Council and Sir Allen Daley for permission to undertake this survey to the head teachers of the schools and their staffs for their willing co-operation, to Mrs M. Kelley, Miss I. Allen, and Miss J. Robinson for their help in the preparation of this report, and to the Medical Research Council for financing the work.

New regulations made by the Minister of Health about health visitors and tuberculosis visitors apply not only to those employed by local authorities, as formerly, but also to the employees of voluntary organizations. They also cover part-time visitors as well as whole-time.

## STURGE-KALISCHER-WEBER SYNDROME OF BILATERAL DISTRIBUTION

BY

C WORSTER-DROUGHT, M.A., M.D., F.R.C.P.

*Physician to the West End Hospital for Nervous Diseases*

Congenital naevi of the face (and body) may be associated with corresponding lesions of the leptomeninges, the latter giving rise to epilepsy—often Jacksonian in type—and in some cases hemiparesis. Sturge, in 1879, reported the case of a girl, aged 6½ years, with an extensive telangiectatic naevus, especially of the right side of the face and head, right-sided buphthalmos, and epileptic attacks starting in the left hand, he concluded that the right side of the brain was also involved in the naevoid condition. Schirmer, in 1860, had already described the case of a man aged 36 with an extensive naevus, especially of the left side of the face, and left-sided buphthalmos, but he made no reference to epileptic attacks or a possible cerebral lesion.

Kalischer, in 1897, reported a case described as a diffuse evidently congenital telangiectasis of the scalp and brain, and in subsequent post-mortem study (Kalischer, 1901) the lesion is described as a blood-vessel tumour (angioma) of telangiectatic character with progressive alteration and participation of veins and capillaries in the growing lesion.

Parkes Weber, in 1922, reported the radiographic appearances of the brain in a typical case which showed a large telangiectatic naevus involving especially the left side of the face, right-sided hemiparesis, and hypotrophy of the affected limbs. X-ray examination of the skull revealed a more or less calcified and apparently "festooned" lesion on the surface of the left cerebral hemisphere. A year later Dimitri (1923), in the Argentine, described the radiographic findings in a similar case.

Other cases in which facial naevi—with or without similar lesions on other parts of the body—have been associated with proved leptomeningeal angiomas, or with symptoms such as epilepsy suggesting the presence of a similar cerebral lesion, have been reported by several observers. The condition may also be associated with buphthalmos ("ox-eye," congenital glaucoma) on the same side as the main cutaneous naevus, as in Parkes Weber's case (1922), three of Cushing's cases (1906 and 1928), and two of Brushfield and Wyatt's cases (1927). Mental deficiency may also be present, as in all Brushfield and Wyatt's cases (1927) and one of Cushing's (1928).

Unilateral intracranial haemorrhage from the abnormal blood vessels of the meningeal angiomatous condition may also occur in early life (or even intrauterine life) and may cause or increase the spastic hemiplegia. The history in one of Cushing's cases suggests this possibility, and in one of Brushfield and Wyatt's cases the left hemiplegia was first noticed after a severe left-sided convulsive attack at the age of 6 weeks.

The actual cerebral lesion would appear to be a capillary angioma of the leptomeninges, as judged from the few post-mortem examinations it has been possible to carry out—e.g., the cases of Kalischer (1901), Strominger (1905), Cushing (1906, 1928), and Brushfield and Wyatt (1927). Thus the meninges are described as "unduly vascular and in all probability representing a naevoid condition similar to that of the skin" (Cushing's first case), the cerebral meninges thickened and excessively vascular (Strominger's case), left cerebral hemisphere covered by a diffuse meningeal angioma (Brushfield and Wyatt). A very vascular condition of the dura mater with adhesions to the leptomeninges has been found at operation (Cushing). The affected cerebral hemisphere is sometimes smaller than

that of the opposite side (e.g., Kalischer's case and one of Cushing's cases).

Parkes Weber (1946) concludes that the condition is due not to any genetic cause but to an "accidental local injury (mechanical, chemical, or physical) to the ovum at some period after fertilization—that is to say, to the embryo during early intrauterine life."

Should an extensive naevus involving mainly one side of the face be present in a patient with contralateral Jacksonian epilepsy or a hemiparesis, the presence of a pial angioma, even if not revealed by calcification, is sufficient to justify the diagnosis. All the cases hitherto recorded appear to have been unilateral. Oppenheim, however, in 1913 reported four cases, in two of which the apparently involved cerebral hemisphere was contralateral to the facial naevus.

The following case showed extensive cutaneous naevi on both sides of the face and body, although more extensive on the right side, which was also hemiparetic. X-ray examination of the skull showed evidence of bilateral intracranial calcification. The epileptic attacks were generalized, although clonic movements usually began and were more pronounced on the right side of the body, also, the child was mentally deficient (amentia).

### Case Report

The patient, a female child, was first seen in December, 1942 at the age of 7½ months. She was a first child, full-term, both the pregnancy and the birth (vertex) being normal. Weight at birth, 6 lb 7 oz (292 kg). Convulsive attacks started at the age of 4 months and have continued at intervals, the fits were mainly but not exclusively right-sided. She has had as many as five fits in one day and has seldom been free from attacks for longer than two or three days. On phenobarbitone, ½ gr (16 mg) t.d.s., the attacks are somewhat reduced in frequency.

The family history showed that a cousin on her mother's side had a cutaneous naevus on the left side of the forehead but without fits. The father and mother were in good health and there had been no miscarriages. There was no consanguinity of the parents and the mother's blood Wassermann reaction was negative.

FIG 1—The patient at the age of 3½ years, showing extensive cutaneous naevi of left side of face and chest and left arm with less pronounced naevus formation on right side of face.

FIG 2—The patient at the age of 4½ years, showing the cutaneous naevus of the upper part of the back on the left side both buttocks—mainly the left—and the left leg

she moved the limbs fairly well. Heart and lungs were normal.

The cerebrospinal fluid was clear to the naked eye but showed 240 red cells, with 6 white cells per cmm, mainly small lymphocytes but with an occasional small endothelial cell, total protein, 140 mg. per 100 ml, with globulin in slight excess. Lange 1211110000 and WR negative. Blood WR negative. X-ray examination of the skull at this stage showed no abnormality.

The fits observed in hospital started with twitching of the right side of the face—at the angle of the mouth and around the eye—and deviation of eyes to the right, the clonic movements spreading to the right arm and leg. There was loss of consciousness with spread of the twitching to the left arm and leg.

#### Subsequent Progress

The patient was seen again a year later (December, 1943), aged 1 year and 7 months. Epileptiform attacks had continued at intervals usually beginning with twitching of the right side of the face, arm and leg as before, occasionally, however, the attack would start with twitching of the left arm. On whichever side the attack started however, both sides were eventually involved, but the right side usually more than the left. The child appeared unconscious for only a minute or so and sometimes consciousness was not lost. The anterior fontanelle was closed. X-ray examination of the skull now showed extensive fine calcification on the left side of the cerebrum and also similar calcification but of lesser extent on the right side.

At the age of 3½ years she could sit up unsupported but was unable to stand. She made no attempt to speak but at times uttered a monotonous cry. She followed a lighted electric torch with her eyes and turned her head at a sound. The cerebrospinal fluid now showed only two small lymphocytes per cmm and a total protein of 40 mg. per 100 ml, both WR and Lange reactions were negative. A blood examination was

On examination (December, 1942), extensive and bright-red capillary naevi were present on the left side of the face, scalp, and upper portion of the trunk, the left arm and hand and the outer portions of the left leg were also involved. On the right side of the face and scalp similar but less extensive naevi were present, on neither side of the face did the lesions extend below the level of the mouth. Further, on the right side smaller naevoid patches were seen on the posterior aspect of the shoulder, scapula, gluteal region, and calf, and on the outer side of both dorsum and sole of the foot (Figs 1 and 2, taken later). Her weight was 14 lb 6 oz (6.52 kg) and she appeared to be mentally deficient. The cranial nerves and optic disks were normal. There was slight spasticity of the right arm and leg, with increased deep reflexes on the right side, but

FIG 3—Skialogram of skull (antero posterior view) showing bilateral intracranial calcification, more pronounced on the left side (Patient at the age of 3½ years)

normal, with 5,040,000 red corpuscles, Hb, 92%, colour index, 0.8, and white cells normal.

An x-ray examination of the skull again showed bilateral intracranial calcification, but more pronounced on the left side than the right. In the antero-posterior view (Fig 3) the calcification is seen in fine linear markings radiating outwards towards the periphery. In the lateral view calcification extends from the cribriform plate to the occipital region, being more pronounced in the fronto-parietal areas (Fig 4).

When seen at the age of 4½ years (January, 1947), she had remained free from fits for several months at a time. When they occurred she might have any number from 1 or 2 to 12 in one day. They remained more or less of the same type, mainly right-sided but spreading to the left side, and sometimes vomiting occurred.

On examination speech was still absent and she made only unintelligible noises. The right arm was spastic, held flexed at the elbow, wrist and fingers, but showed a fair degree of voluntary movement. The right arm jerks were all brisker than those on the left. The left arm was used more than the right. The abdominal reflexes were present, left brisker than right. There was slight adductor spasm of the legs, the right leg being more spastic than the left. Voluntary movements were present but were weaker and of less range in the right leg, which was 2 in (1.9 cm) shorter than the left. There was a tendency to

FIG 4—Skialogram of skull (lateral view), showing intracranial calcification extending from the supra-occipital to the frontal region (Patient at the age of 3½ years)

talipes caicansus on both sides. She made no attempt to walk, but could stand when supported with both legs adducted. Occasionally restless movements of all limbs were observed. The knee and ankle jerks were brisk, right greater than left and plantar reflexes indefinite. Heart normal, pulse rate 76, and blood pressure 105/70.

### Commentary

I am not aware of any previous record of a case of Sturge-Kalischer-Weber syndrome showing bilateral intracranial calcification. Cases of extensive cutaneous naevi on both sides of the body, usually more continuous on one side and patchy on the other, in association with Jacksonian epilepsy are occasionally encountered. One such case under my care is described in an addendum to Parkes Weber's paper of 1929, in this case, no intracranial calcification was demonstrable on x-ray examination. In the case now reported the calcification is more extensive and more intense on the one side (left cerebral hemisphere), than on the other, and this corresponds to definite hemiplegic signs in the spasticity of the right arm and leg and the increased deep reflexes. Similarly, the epileptiform attacks usually begin on this (right) side, and even when more generalized the right side is the more affected. The blood found in the cerebrospinal fluid at the first lumbar puncture at the age of  $7\frac{1}{2}$  months was almost certainly due to contamination at the time of lumbar puncture (no doubt resulting from intense local vascularity) rather than to a recent subarachnoid haemorrhage from the intracranial angioma, as the red cells were quite fresh and there was neither haemolysis nor xanthochromia. Then again, the cerebrospinal fluid examined at the age of  $3\frac{1}{2}$  years was quite normal.

The calcification of the meningeal angioma evidently began between the ages of  $7\frac{1}{2}$  months and  $1\frac{1}{2}$  years, since no x-ray abnormality was seen at the earlier age, but a year later intracranial calcification was demonstrated on both sides, the more profound lesion of the left cerebral hemisphere showing the more extensive and denser calcification.

Presiding at a conference of the Tuberculosis Association in Belfast, Dr Frederick Heaf, Director of the London County Council tuberculosis services, said the organization in Ulster for dealing with the disease was the envy of the profession in England. Dr Brice Clarke, Director of the Northern Ireland Tuberculosis Authority, informed the conference that there were 1,200 beds in tuberculosis hospitals in Ulster, as well as a number of beds in general hospitals for tuberculosis patients. Seven hundred additional beds were planned and 250 of them would be ready within the next twelve or eighteen months. A children's orthopaedic hospital was being built and an infants and children's hospital for pulmonary cases was being developed. It was hoped to have five or six clinics in Belfast and thirteen in other parts of Ulster. In addition, a contract had been placed for 100 rest chalets. Since June, 1945, 93,000 persons had been examined by the mass radiography unit in Belfast and a second unit had been ordered.

## POLIO-ENCEPHALITIS

BY

E. G. BREWIS, MD, MRCP, DPH

AND

C. NEUBAUER, MD

(From the City Hospital for Infectious Diseases  
Newcastle upon Tyne)

The 1947 epidemic of poliomyelitis has again attracted attention to the question of polio-encephalitis, and there is no doubt that considerable confusion prevails concerning the definition of this condition. McAlpine (1947) stated that "during this epidemic the presence of nystagmus, photophobia, and neck rigidity in a patient who has been ill for a few days with headache and fever was considered sufficient evidence for the diagnosis of polio-encephalitis. Murray (1947) suggested that the brain-stem form of the disease should be regarded as an extension of the spinal type, and that the notification of polio-encephalitis as a separate condition should be discontinued.

Rothman (1931), in an excellent review of the situation at that time, stated that "the exact status of polio-encephalitis (using the term to mean cerebral and not bulbar involvement) and its relationship to the spinal form of infantile paralysis remains nearly as unsettled now as it was at the time of its description." This statement holds true to day. It is hardly surprising that this should be so when it is remembered that the name was first given by Strumpell in 1885 to a form of cerebral paralysis in children which, although displaying many of the manifestations of poliomyelitis, was probably due to toxic action on the cerebral vessels causing thrombosis or haemorrhage without evidence of encephalitis (Ford and Schaffer, 1927).

It has been stated that increased tendon reflexes, absent abdominal reflexes, and extensor responses are evidence of cerebral involvement in poliomyelitis (Kiss and Fenyès, 1936). These signs, and the combination of spastic and flaccid paralyses, may be due to pressure on the pyramidal tracts from inflammation and oedema in the white matter of the cord.

Scheinker (1947), in a detailed study of six cases, found that no part of the central nervous system entirely escaped damage, and that the medulla, pons, mid-brain, and cerebellum were involved in every case, while the cerebral cortex was not affected at all. He also found that inflammatory changes were intense but neuronal destruction rare in the higher centres, in contradistinction to conditions in the anterior horns. Bodian (1947), reporting on 24 human cases, stated that to the pathologist all cases of poliomyelitis were encephalitic, that some areas of the brain were never affected but the main cerebral changes were from the brain stem to the hypothalamus and thalamus. So far as the motor cortex was concerned, Bodian considered that only in rare cases were the lesions severe enough to cause clinical signs, and that spastic and psychic sequelae were not cortical in origin—nor were stupor, disorientation, and coma—but were produced by areas of focal softening in the basal centres.

The following case under our care appeared to show encephalitic manifestations and involvement of lower motor neurones.

### Case Report

A girl aged  $17\frac{1}{2}$  had been well until Nov. 9, 1947, when she suddenly developed a cold and generalized headache. On Nov. 12 vomiting started, being repeated several times, and she was admitted to hospital as a case of suspected meningococcal meningitis.

diagnostic value than cervical cultures. In 32 cases both swabs were positive, but 18 urethral swabs were positive when the corresponding cervical swab was negative, and only eight cervical swabs when the urethral swab was negative.

#### *Trichomonas*

During this investigation it was incidentally discovered that *T. vaginalis* remained alive and active in the transport medium. The detection of these organisms was simple. A drop of peptone-water suspension prepared from a swab was placed on a clean slide under a coverslip and examined microscopically with reduced illumination. Frequently the presence of the parasite could be detected with a 2/3-in. (1.7-cm) objective ( $\times 60$ ) by its active jerking movements, and brisk flagellar movement could be seen regularly with a 1/6-in. (0.4-cm) objective ( $\times 240$ ). To determine the reliability of this method of examination, 401 consecutive specimens, including a number from males and children, were examined in parallel by the simple wet-film method and after Leishman staining. To make the examination of direct comparative value the wet film was examined first and the result recorded as positive only if distinct movement, either organismal or flagellar, was seen. Then the coverslip was removed carefully, the fluid on the slide concentrated on as small an area as possible and fixed in the usual manner. Thus the same specimen was examined by the two methods. Staining and further examination were carried out independently by another worker with many years' special experience in this type of investigation. In spite of the apparent advantage of the stained film (Table III) it was found that in only two instances were more

TABLE III—*T. vaginalis* Comparison of Stained Film and Wet Film

Stained Film Wet Film	+	-	0	0

Total	81	28	12	260

than one or two trichomonads present in the 28 positives not detected by wet film, so in view of the latter's simplicity it was adopted as a routine. In all, 710 consecutive specimens were examined by this method (Table IV). Of 312

TABLE IV—Incidence of *T. vaginalis*

	Urethra		Cervix (Adults)	Vagina (Children)
	Male	Female		
Positive	2	60	120	2
Negative	39	237	191	59

adult women examined *T. vaginalis* was found in 139. The incidence in patients with gonorrhoea was 20 out of 45, in patients with non-specific leucorrhoea 73 out of 144—in both instances approximately 50%. However, in a series of 123 women examined as a test for cure and in whom no clinical symptoms were manifest 46 were found to be positive—an incidence of more than 37%.

#### Discussion

The success and simplicity of the above transport method recommend its use in clinical venereal disease practice. The principle that the prevention of oxidation helps to maintain gonococcal viability in transport material has been established by experience. Nevertheless, in common with many other newly established techniques unexpected difficulties have arisen. It has been found that many batches of agar now available are unsuitable, perhaps because of

their content of a bacteriostatic or bactericidal substance described by Ley and Mueller (1946). Recent experiments suggest that these difficulties may be circumvented comparatively simply, and it is hoped to publish shortly a description of the amended technique. The difficulty associated with the overgrowth of other bacteria does not arise in the method described, but the discovery of an effective selective bacteriostatic agent would still be of great benefit in culture by allowing a much larger inoculum to be used.

The value of cultural investigation of gonorrhoea is now probably universally accepted. Certainly in female gonorrhoea the difficulties which face the clinical worker dependent solely on the results of smear examinations cannot be overemphasized. Most observers will agree that a smear from an average mixed infection in a female always shows the presence of organisms with some morphological resemblance to gonococci. Many of these are Gram negative coccobacilli which have often a distinct tendency to coccil morphology in exudates. De Bord (1943) described many of the organisms which may be mistaken for gonococci by simple microscopical examination. *Neisseria* other than gonococci are not uncommon, but in culture their identity is readily established. In the above series such organisms were isolated on three occasions.

Many striking examples of the advantage of culture have been noted in the above investigation. Six successive smears from one woman were negative, yet the first culture taken was positive. In many women known to have been in contact with a case of gonorrhoea no clinical signs were discovered yet positive cultures were obtained. Coincident with this or soon after frank clinical evidence of infection appeared in some of the patients. In spite of the numerous successes however, failures have also been recorded. Some of these are possibly explainable by adventitious factors. A number of patients were found to have been swabbed in error with a weak antiseptic lotion before the specimen was taken. The persistence of this old clinic routine was only discovered late in the investigation when the patients affected could no longer be traced. Again specimens for smear examination were always taken first and this practice may have weighted the series in favour of smear examination. Nevertheless, we are convinced that a few strains of gonococci are peculiarly difficult to grow. Such strains have been recorded by Linkford *et al.* (1943). Using media similar to those we employed Weller and Williams (1946) obtained cultures from only 76% of known positives. Media which are supposed to give better results are now being investigated but it seems unlikely that complete success will be achieved so long as gonococci have to compete on equal terms with more vigorous contaminating bacteria. It is probably the consensus of modern opinion that even the well established Loeffler's serum for *Corynebacterium diphtheriae* fails in from 5 to 30% of cases, and greater success has been obtained only since the introduction of potassium tellurite, a selective bacteriostatic agent. In the culture of the gonococcus final success awaits the introduction of such an agent. Perhaps some of the new antibiotic substances may be suitable for the purpose and it is unfortunate that workers in this field so often seem to abandon further investigation of bacteriostatic substances which prove inactive *in vitro*.

At present we believe that smear and culture investigations are complementary and that successful diagnosis and control of gonorrhoea, in females at least demand the application of both. The difficulty of applying cultural methods to specimens taken from dispersed clinics has been largely resolved by the transport method described and we hope that this will prove of value to other workers.

The evidence presented in this paper of trichomonad infestation will not increase clinical belief in the pathogenic importance of this parasite. The very high incidence of the organism in the female genital tract without any inflammation or discharge may suggest very legitimately that its presence in inflammatory exudates is coincidental rather than causative. It may also be pointed out that the detection of *Trichomonas* was merely incidental to this investigation and that the specimens were not those generally considered best for the purpose. It is quite possible that in some women vaginal irritation may be caused by *T. vaginalis*, but to ascribe to it the importance it commonly gets because of its frequent presence in leucorrhoea is an example of *post hoc ergo propter hoc* reasoning which cannot be substantiated by the facts at present available. Further investigation of its occurrence in normal women is obviously desirable. The transport method described allows the investigation to be carried out more leisurely and conveniently than has hitherto been regarded possible.

### Summary

A method of transporting specimens for the diagnosis of gonorrhoea is described. By its use facilities for culture can be made available to all clinics within a "time distance" of 24 hours from a laboratory.

The method is at the same time applicable to the detection of *T. vaginalis*.

In the above investigation of gonorrhoea 139 positives out of 184 were found by smear examination alone and 158 by culture. The combination of smear and culture discovered 24% more positives than smear examination alone, and culture alone 10% more than smear.

*T. vaginalis* was found in approximately 50% of women with vaginal discharges and in almost 40% of women in whom no evidence of inflammatory disorder was evident and who were examined as a test for cure of gonorrhoea.

**FOOTNOTE**—Since this paper was written an alteration in technique has been found necessary owing to the bactericidal action on *Neisseria* of certain later batches of agar used in preparing the transport medium. This property is apparently the same as that described by Ley and Mueller (1946) and is particularly prominent in the absence of nutrient material which is a feature of the medium described. The inhibitory effect can be neutralized by charcoal (Stuart, 1947), but charcoal cannot be incorporated in the medium without absorbing the methylene-blue reduction indicator. Accordingly, swabs are prepared as described above and then dipped in a 1% water suspension of finely ground charcoal (B D H blood charcoal and "norit" have been found equally suitable) before being dried and sterilized. Results from a year's experience with these charcoal-impregnated swabs are significantly better than those given above, and suggest that even when the agar is apparently free from inhibitor this alteration in technique is desirable.

## THE ROLE OF ABDOMINAL TRAUMA IN ACUTE APPENDICITIS

BY

W RUTHERFORD BLACK, FRCSEd

Tutor in Surgery University of Bristol

Abdominal trauma as a causative or contributory factor in the development of acute appendicitis occasionally merits attention, as the symptoms of that condition have appeared very soon after receipt of the injury. Boyd (1947) states that "there is no doubt that a blow on the abdominal wall may occasionally precipitate an acute attack of appendicitis". J B Murphy (1908) cites an analysis by von Neumann of 152 cases of acute appendicitis in 10 of which trauma, either from direct injury to the abdomen or from strain during lifting, was a causative factor. Romanis and Mitchner (1937) observe that "in some cases injury undoubtedly stimulates an attack, but this is rare. It is possible that a twist, blow, or strain will cause a concretion to move and completely block the appendix".

The role of trauma as an exciting factor in the production of acute appendicitis assumes importance from the medico-legal aspect when abdominal injury received during employment is advanced to procure compensation in the courts. Quite recently two cases of acute appendicitis have been encountered immediately after abdominal injury. As both occurred in children of school age, where the motive for procuring compensation did not arise, it is of interest to record them.

### Case 1

A schoolboy, aged 14, on mounting his bicycle at 9.50 p.m. on Feb 15, 1948, missed the pedal and fell forward, and the left handlebar struck him forcibly in the centre of the epigastrium. He had momentary upper abdominal pain, but almost immediately mounted his cycle and reached his home at 10.5 p.m. When in bed, about 10.30 p.m., he experienced soreness in the upper abdomen, but fell asleep. He woke about 3.30 a.m. with generalized colicky abdominal pain, and vomited, after which the pain localized in the right iliac fossa. His pain persisted, and he vomited twice more before his admission to hospital at 10 a.m. on Feb 16, twelve hours after the receipt of the injury. He had not had his bowels open since his injury, there was no abnormality of micturition, and there was no previous history of a similar attack.

On examination the temperature was 99.4° F (37.4° C), pulse 84 respirations 16. The patient was pale and evidently in pain. His tongue had a light yellow fur, and there was slight fetor oris. The abdominal wall was immobile on respiration with resistance and tenderness in the centre of the epigastrium above the umbilicus. Tenderness and guarding were greatest in the right lower abdominal quadrant, where "release pain" was also elicited. There was no loss of liver dullness. Rectal examination revealed tenderness maximal towards the right side of the pelvis. The urine contained no abnormal constituents. The blood pressure was 120/90.

A provisional diagnosis of a ruptured hollow viscus, probably upper jejunum, was made, and laparotomy was decided on.

**Operation**—Under thiopentone, 0.5 g nitrous oxide-ether and oxygen anaesthesia, the abdomen was opened through a right paramedian incision, greater in extent above the umbilicus than below. The stomach, duodenum, and duodeno-jejunal junction were normal. There was a very fine frothy exudate

on the surface of the duodenum and upper jejunum, but no lesion was found here or in the ileum. The gall bladder and pancreas were normal. The caecum was delivered and immediately a gangrenous appendix was seen. It had not perforated. Appendicectomy with invagination of the stump was performed and the abdomen closed without drainage.

On section the appendix showed a hard faecalith impacted about  $\frac{1}{2}$  in (1.25 cm) from the base. Distal to this point the lumen of the appendix was filled with foul smelling dark blood-stained mucus. The mucosa was gangrenous and showed patchy ulceration. Recovery was uninterrupted, and the patient was discharged on Feb 26.

### Case 2

At 3 p.m. on March 10, 1948 the patient a schoolgirl aged 14, slipped while turning a somersault on the horizontal bar, which struck her across the centre of the abdomen. She continued with her exercises, but about three hours later experienced colicky abdominal pain, which became worse during the night. She vomited twice, after which the pain localized in the right iliac fossa. She had diarrhoea twice during the night. There was no abnormality of micturition or of menses. She had no history of a previous similar attack. The patient was admitted to hospital at 2.30 p.m. on March 11, 24 hours after receipt of the abdominal injury.

On examination the temperature was  $100^{\circ}\text{F}$  ( $37.8^{\circ}\text{C}$ ), pulse 100, respirations 20. The patient was flushed and had a rather dry tongue. Fœtor oris was present. There was marked tenderness with muscular guarding and "release" pain confined to the right iliac fossa. Rectal examination revealed well-defined tenderness towards the right side of the pelvis. The urine contained no abnormal constituents. The blood pressure was 110/80. A diagnosis of acute obstructive appendicitis was made.

**Operation**—Under thiopentone 0.5 g, nitrous oxide-ether and oxygen anaesthesia, a McBurney muscle splitting incision was made, and a gangrenous appendix lying towards the brim of the pelvis was found. It had not perforated. Appendicectomy with invagination of the stump was performed. The abdomen was closed without drainage. On section the appendix was found to have a faecalith impacted in its lumen, just distal to its base. Beyond this point the appendix contained light reddish brown mucus. The mucosa showed gangrenous patches. Recovery was uneventful, and the patient was discharged home on March 18.

### Commentary

It is interesting to observe that both cases had a faecalith impacted in the lumen of the appendix. It is reasonable to conjecture that the increased intra-abdominal pressure resulting from the abdominal injury might conceivably force a faecalith already formed at the base of the appendix more distally into the lumen, thereby precipitating an attack of acute obstructive appendicitis.

One might justifiably conclude in a case of acute appendicitis immediately following abdominal trauma, where the presence of a faecalith impacted in the lumen of the appendix was found at operation that the injury was a contributory and causative factor of the attack.

I should like to thank Mr D. G. C. Tasker for his interest in and advice on this paper.

On July 6 x-ray and electro medical apparatus worth £3,500 was officially handed over to the Children's Clinic of Poznan University, Poland by the General Sikorski Memorial Hospital Fund. A ceremony was held at Century House (Philips Electrical, Ltd.), London makers of the equipment. His Excellency the Polish Ambassador, representing Poznan University, received an illuminated scroll commemorating the event from Mrs E. d'A. Wilks and Major Rowland Sanders, Trustees of the General Sikorski Memorial Hospital Fund.

## Medical Memoranda

### A Case of Intrauterine Amputation due to External Trauma

The following case is recorded because of its apparent rarity. Search of the literature has failed to reveal any case exactly similar, although undoubtedly such cases have occurred—e.g., during air raids—without being recorded.

### CASE HISTORY

A second gravida aged 27 was admitted to hospital at 3 p.m. on March 30, 1946, about one and a half hours after a motor accident in which she had been thrown out of the rear side window on to the grass verge, where she had been pinned down for about 30 seconds by the running board of the overturned car, which had come to rest across her abdomen. She stated that she was about 5½ months pregnant, the pregnancy being normal, as had been her previous pregnancies and confinement. She complained of constant severe pain over the whole abdomen, there had been no vomiting or loss of consciousness, and she felt quite well apart from the abdominal pain.

On examination the temperature was  $97.6^{\circ}\text{F}$  ( $36.4^{\circ}\text{C}$ ), pulse 74, respirations 18, B.P. 125/80, there were no abnormal physical signs in the respiratory, cardiovascular and central nervous systems. Examination of the abdomen showed a tender swelling corresponding in size to a 24 weeks pregnancy, the foetal heart was heard faintly, but no foetal movements were detected. During the patient stated that she had felt movements since the accident. There was a transverse linear bruise at the level and to the right of the umbilicus overlying an area of deep tenderness. There was no abdominal rigidity or muscular guarding and no evidence of free fluid in the peritoneal cavity. The uterus was not actively contracting and gave no sensation of "woodiness". Bleeding per vagina did not occur and a vaginal examination was not made.

Morphine, 1½ gr (11 mg) was given every four hours and the patient passed a quiet night. The following morning her condition was not materially altered. There was no abdominal pain. The foetal heart was still thought to be heard but the height of the uterus had increased to that of a 28 weeks pregnancy and there was slight vaginal bleeding. Accidental haemorrhage was provisionally diagnosed, and conservative treatment consisting of nuchal, 1½ gr (0.1 g) eight hourly, progesterone 1 ml on alternate days and "ephynal," 1 tablet three daily, was given for three days. During this time the foetal heart was not heard, there was no increase in size of the uterus, and no further vaginal bleeding.

Five days after admission (April 3) she had a brisk vaginal haemorrhage, losing approximately 30 oz (850 ml) of bright blood. Rectal examination revealed that the cervix was three fingers dilated and that the membranes were bulging. The patient was having weak but regular pains and the height of the fundus had fallen to the level noted on admission. Twenty-four hours later there was spontaneous delivery of a 26 weeks foetus, followed immediately by the placenta and about 10 oz (280 ml) of old blood. She was given 1 ml of ergometrine intramuscularly and the uterus contracted firmly.

The foetus was normally developed and showed early signs of maceration. The left leg was almost completely severed from the body at the level of the anatomical neck of the femur remaining attached only by the fibres of the quadriceps muscle. The remaining muscles had been neatly divided at the level of fracture of the femur. Apparently the foetus had been lying in the R.O.P. position at the time of injury, whereby the impact of the running board of the car had been transmitted to the posterior surface of the left thigh, resulting in an almost complete traumatic amputation of the limb in utero.

A detailed examination of the foetus was impossible, as it was unfortunately disposed of by mistake before further examination could be made.

It is worthy of comment that the foetus, which was relatively well protected by its position and its covering, should have suffered severely, while the uterine and abdominal walls which were subjected to the direct impact showed minimal damage.

Our thanks are due to Mr D. W. Currie consultant obstetrician and to Dr W. McIntosh medical superintendent St James's Hospital, Leeds, for permission to submit these notes for publication.

## Reviews

### RECENT PATHOLOGY

*Recent Advances in Pathology* By Geoffrey Hadfield, M.D., F.R.C.P., and Lawrence P. Garrod, M.D., B.Ch., F.R.C.P. Fifth edition (Pp 363, 60 illustrations 21s) London J and A Churchill 1947

When a book has reached a fifth edition it is interesting to turn back to the original volume and see how the subject has progressed. The first edition of "Hadfield and Garrod" came out in 1932, its deliberate purpose to chronicle recent advances, and comparison gives us a record of the new facts which have been discovered in the last sixteen years and, what is of greater interest, the changes in thought and method that have occurred within this period. The first impression is of an increasing complexity—pathology seems so much more difficult than it used to be—and an increasing devotion to detail with a corresponding blurring of the stronger lines of the picture. A second and a very welcome one, is a certain loss of didacticism and of that tendency to catalogue causes and classify effects into those neat echelons, battalions, and regiments so dear to the heart of the examinee.

In this period of its existence the book has shrunk from 390 to 351 pages, and owing also to the use of inferior paper it is a slimmer and altogether handier book than it was in 1932. The general trend has altered remarkably little, only one or two new full subjects have been considered—e.g., the reticulosos and reticulo-sarcoma, and recent work on inflammation and allergy—but the matter is completely different even though chapter headings may remain the same. This comparison of what was recent with what is evokes some unmanly nostalgia and provides opportunity for gentle cynicism. "Nephritis" is perennially new, and, as before, the recent advance is one of nomenclature. Gone are Bright, Gull and Sutton, Samuel West, McLean, Volhard and Fahr, Dorothy Russell, John Gray, Dunn, Fishberg, and the rest—and Ellis is the new prophet. *Où sont les neiges d'antan?* And yet the "mixed types" are still with us to confound the most ingenious of nosologists, and the stage awaits the next performer. Gone are tissue culture, vitamins, tumours of the central nervous system, and encephalitis and lead therapy.

"Half the marvels of my morning, triumphs over time and space  
Staled by frequency, shrunk by usage into commonest commonplace"

*Spiroptera neoplastica* shuffles away under the alias of *Gongylonema* and the authors pronounce its valedictory with faint regrets. What a romantic story it makes for us! In its heyday it got Fibiger a Nobel prize—surely justice demands some condign reward for Passey. The gaps have been filled by a good review of recent work on inflammation and related conditions, a full account of hepatitis and liver necrosis, and an excellent survey of the cancer problem. It would have been easy for the writers to have resorted to scissors and paste, but they have withstood this temptation and have given the reader a summary of new facts and views and also their own valuable judicial comments on most questions.

It would hardly be in keeping with custom to close this review without some criticism, and after patient research the writer has discovered that Cullumbine (p. 7) is spelt for the harlequinade (no doubt the professor of physiology at Colombo is accustomed to this—yet it may irk), and that Fig. 5 has lost much of the freshness it had in the Bart's Hospital Reports of 1939. The style and language of the book are such as would be expected from teachers of the experience of the authors, but we wince a little at "benzolised" (of rabbits) and recoil ("definitely") from "cancerisation". This is a book which every aspirant for higher medical qualifications must read and every teacher of pathology should own.

J HENRY DIBLE

### DEVELOPMENT OF CEREBRAL CORTEX

*The Postnatal Development of the Human Cerebral Cortex* By J. LeRoy Conel, Professor of Anatomy Boston University School of Medicine. Volume 3. *The Cortex of the Three month Infant* (Pp 158, 104 plates \$12.50 or £3.10s) Massachusetts Harvard University Press London Geoffrey Cumberlege (Oxford University Press) 1947

The third volume of Dr Conel's comprehensive study of the post-natal development of the human cerebral cortex has now appeared. It comprises a detailed description of the cyto-architecture of the cortex of the three month-old infant, and like the preceding volumes is documentary rather than explanatory. Almost half the volume is made up of an atlas of excellently produced photomicrographs illustrating the various areas of the cortex as they appear in sections stained with cresyl violet, the Cajal silver technique, and the Golgi-Cox method. This book will undoubtedly be useful as a work of reference for those concerned with the study of the maturation of the central nervous system and its functions.

### OPHTHALMOLOGY IN GENERAL PRACTICE

*Clinical Ophthalmology for General Practitioners and Students* By H. M. Traquair, M.D., F.R.C.S. Ed. (Pp 264, 72 illustrations, including 8 coloured plates 25s) London Henry Kimpton 1948

No one but Traquair would have had the courage to write a treatise on "ophthalmology without an ophthalmoscope". The purpose of the book is to help the general practitioner (who is assumed not to know how to use the ophthalmoscope—a shocking assumption, but too often true) to advise his ophthalmic patients in a common-sense way and without specialized techniques. The book is in no sense a textbook of ophthalmology but the author emphasizes common ocular complaints and symptoms and indicates their importance and when expert help should be sought. Within these somewhat severe limitations the book is very readable and full of practical teaching. The most valuable chapter is probably that on common misconceptions and prejudices, where the author admirably discusses popular ideas on such topics as the effect of near work on myopia, the "weakening" influence of spectacles, the "sin" of reading in bed, and so on. The book is worth reading by both the general practitioner and the specialist, but it would have been happier not to dedicate it to the medical student, who surely should not start his career without an ophthalmoscope.

STEWART DUKE-ELDER

### MENTAL HEALTH

*Personal Mental Hygiene* By Dr Thomas Verner Moore, O.S.B., M.D., Ph.D. (Pp 331 21s) London William Heinemann (Medical Books) Ltd 1947

The author's object is to show that high ideals and principles can do much to ensure emotional stability and so enable a man to avoid the development of both psychoses and psychoneuroses. Written by a Catholic priest who is professor of psychology in a Catholic university, it is natural that Catholic doctrines and observances should constitute the high ideals and principles. The author's thesis involves two premises—namely, that every one can or should accept Catholic teaching and the Catholic way of life, and that if from the start the training, beliefs, and practices of a person are right he should not fall mentally ill. While no one will deny that the Catholic principles and way of life are of a high order it is improbable that everyone can accept or practise them, and even if they were to it seems unlikely that mental illness would disappear.

None the less, since this book is about personal mental hygiene, what the individual can do for himself, we must not complain if the treatment of the subject appears superficial and allows too little for deep seated constitutional factors and the subsequent struggle between what the Freudians would call the id and the superego, a struggle which cannot be altogether prevented or controlled by outside influences. Thus in discussing the paranoid reactions the author suggests that training in tolerance would make much difference yet it seems unlikely that a paranoiac would be able to control his ideas of reference however much he strove to develop tolerance from however

early in age, for the good reason that the paranoiac cannot be tolerant. We detect a certain bias not only religious but patriotic when he cutes Hitlerite Germany as the paramount unstable nation a proposition with which we might well agree, but should we agree so readily that the U.S.A. is the paramount example of the stable nation? The author illustrates his points both from the lives of his own patients and from those of famous men. Abraham Lincoln overcame early depression and failure by faith and personal effort and Joyce Kilmer by overcompensation and reinterpretation—regarding suffering as an interesting experience and even 'great fun'. On the other hand Oliver Goldsmith suffered from unrestrained emotional life without any definite goal, Dante Gabriel Rossetti from a failure to resist to evil influences and Swinburne from prandering to his mischievous impulses while Francis Thompson recovered from his drug addiction by religious sublimation.

The author compares the family to a monastic community and contrasts the influence of schools which impose discipline with those that allow their pupils to follow all their impulses. There is no doubt that there would be much less mental trouble and unhappiness if we could ensure that all children were brought up in happy loving well regulated homes and if we could avoid alcohol syphilis, and arteriosclerosis though we might not agree with the author's assertion that the last was due almost exclusively to excessive smoking. Altogether there is much sound sense in this book and all could read it with profit, though the appeal of the author's contentions will be especially appreciated by his fellow Catholics.

R. G. GORDON

## HUMAN REPRODUCTION

*Fundamentals of Human Reproduction* By Edith I. Potter M.D. Illustrated by Alvin W. Meyer, F.A.A.R. (Pp. 231 illustrated \$3.50 or 21s) New York and London McGraw Hill Book Company, Inc.

This book is one of a series written for nurses and the authoress is lecturer to the nurses at the Chicago Living in Hospital. Her intention is to present an easily readable book on reproduction in the human female. She discusses the fundamentals of cytology and genetics the anatomy and physiology of the reproductive system the mechanism of implantation intrauterine development and the formation of the body organs. Finally she gives an account of the birth and future life of the infant.

The book is remarkably easy to read for the style is not particularly condensed and the authoress emulates Gibbon in collecting a large amount of material into a little space. The line drawings are very good and the photographs well chosen. It is an outstanding book and should have a wide appeal. It will interest senior obstetricians and gynaecologists for it is remarkably up to date and the author has described the modern problems of meiosis genetics and heredity simply and accurately. It is suitable for senior medical students particularly those reading for the primary fellowship examination and seems to contain far more than is required for the nursing profession.

WILFRID SHAW

*A Manual of Fractures and Dislocations* by Dr Barbara Bartlett Stimson (Henry Kimpton second edition 17s), is designed for medical students and general practitioners. It contains in the first sixty pages which are devoted to general considerations many excellent and clearly stated principles—in fact almost all the good conservative doctrines which should form the basis of intelligent management of fractures. However, many important fractures and their complications are discussed very briefly indeed. A few examples will serve to illustrate this. Fractures and dislocations of the spine including cord injuries occupy six pages, fractures of the pelvis two pages, which include two sentences on visceral injuries. The author describes pinning of fractures of the femoral neck in one sentence and Volkmann's ischaemic contracture in one short paragraph. That there is in places some disproportion may be seen from the fact that in contrast to these there are five pages on dislocations of the clavicle. Description of the individual fractures is clear and should be easily understood. The space devoted to the pathology of each fracture and dislocation might perhaps have been put to better use. The book is copiously illustrated with good line drawings. As a primer for medical students or as a fracture book for nurses it should prove useful.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Manual of Leprosy* By I. N. J. C. M. G. C. I. E. M. D. I. R. C. S. Ed. (Pp. 208 17s 6d) Edinburgh Livingstone 1945  
A practical manual of diagnosis and treatment

*Textbook of Chiropody* By M. J. McKenzie Swanson R. Litt. I. Ch. S. (Pp. 212 20s) Edinburgh Livingstone 1947  
An illustrated practical account of chiropody

*A Way to Natural Childbirth* By H. Heardman (Pp. 124 7s 6d) Edinburgh Livingstone 1948  
Practical instructions for the mother to be and physiotherapists

*Aseptic Treatment of Wounds* By C. W. Walter A. B. M. D. (Pp. 372 4s 6d) New York Macmillan 1948  
An account of the technique of asepsis in surgery

*Chest Examination* By R. R. Trail M. C. M. A. M. D. F. R. C. P. 3rd ed. (Pp. 170 12s 6d) London Churchill 1948  
A manual for the medical student

*Reproduction and Survival* By R. C. Brown, M. B. M. S. I. R. C. S. I. R. C. O. G. (Pp. 108 6s) London Arnold 1948  
An account of the physiology of reproduction, fertility and sterility and labour as an instrument of natural selection

*The Beginnings of Modern Medicine in Madras* By D. V. S. Reddy (Pp. 244 5 rupees) Calcutta Thacker 1947  
A history of modern medicine in India

*Aids to Biology* By R. G. Neill, M. A. 2nd ed. (Pp. 279 6s) London Baillière Tindall and Cox 1948  
Intended for medical students and others

*The Ides of March* By Thornton Wilder (Pp. 198 9s 6d) London Longmans 1948  
A novel set in the Rome of Julius Caesar

*Acute Intestinal Obstruction* By Rodney Smith M. S. F. R. C. S. (Pp. 259 18s) London Arnold 1948  
A manual of diagnosis and treatment

*Dental Practice Management* By S. L. Drummond Jackson (Pp. 370 30s) London Staples 1948  
An account of the administration and business management of dental practice

*The Yearbook of Psychoanalysis* Edited by S. Lorand M. D. et al. Vol. 3 (Pp. 309 30s) London Imago 1947  
Papers on different aspects of psychoanalysis

*The Neglected Child and His Family* By a subcommittee of the Women's Group on Public Welfare (Pp. 140 5s) London Geoffrey Cumberlege 1948  
A study of the neglected child in his home and of the relevant law and administration

*The Case of Augustus D. Este* By D. Firth, M. A. M. D. F. R. C. P. (Pp. 58 6s) Cambridge University Press 1948  
A collection of letters and diaries written by or relating to Sir Augustus d'Este, who had disseminated sclerosis giving an early clinical account of the disease

*That Which is Caesar's* By H. G. Woodley (Pp. 156 8s 6d) Oxford Pen in Hand 1948  
Comments on the treatment of mental disorder by one who was confined to a mental asylum for a year

*The Acute Bacterial Diseases* By H. F. Dowling, M. D. F. A. C. P. (Pp. 465 32s 6d) London Saunders 1948  
A textbook of diagnosis and treatment

*Nature's Way* By R. Millar (Pp. 55 3s 6d) London Watts 1948  
Described as 'a means of health without medicine'

## CHLOROMYCETIN

The latest antibiotic to gain a place in the chemotherapy of disease is chloromycetin, which was originally obtained from a streptomycetes found in the soil of a field near Caraças, Venezuela, by Ehrlich and his colleagues<sup>1</sup>, it has now also been isolated from a streptomycetes found in a compost heap in Illinois<sup>2</sup>. A preliminary examination of the antibiotic activity of chloromycetin by Smadel and Jackson<sup>3</sup> showed that in addition to having some action on viruses of the psittacosis-lymphogranuloma group it inhibited the growth of a number of pathogenic rickettsiae both in experimental animals and in developing chick embryos. Chloromycetin is active when given by mouth, and Ley and his co-workers<sup>4</sup> showed that a dose of 10 g by mouth daily for 11 days caused no abnormal signs or symptoms. The substance is found in the greatest quantity in both blood and urine two hours after an initial dose of 10 g by mouth, the estimation being carried out by a method of microbiological assay which involves inhibition of the growth of *Shigella paradysenteriae* (Sonne). After two hours the blood levels steadily fall from about 6 µg per ml till at eight hours detectable amounts are no longer found. Urine levels of the drug are approximately 200 µg at two hours, falling to 50 µg per ml at eight hours and remaining at this level for the next 10 days of treatment. When an initial dose of 20 g of chloromycetin is given blood levels are 10 µg per ml at two hours and above 5 µg at the end of eight hours. Urine levels are highest at two hours, reaching values of 380 and 670 µg per ml and falling to about 10 µg per ml at eight hours. The fact that appreciable amounts of chloromycetin are found in blood and urine 30 minutes after being given by mouth indicates that the antibiotic must be rapidly absorbed from the gastrointestinal tract. Approximately 10% of the total amount of chloromycetin given daily was recovered in active form in the urine of volunteers, much must therefore be metabolized. No signs or symptoms attributable to toxicity were observed in three volunteers during or after the treatment, examination of the blood and urine showed no abnormalities. Since the drug is rapidly excreted or inactivated its administration at fairly frequent intervals is obviously necessary.

The activity of chloromycetin and its lack of toxicity have been confirmed by Smadel and his colleagues,<sup>5</sup> who used it in the treatment of cases of typhus fever in Mexico. Three adults and one child were suffering from epidemic

louse-borne typhus and one child from the murine type. One of the adults was very severely affected and was not treated till the seventh day of illness, then 15 g was given by mouth, followed one hour later by 15 g and thereafter 0.2 g every two hours for four days and subsequently 0.2 g every three hours for three days. The other two adults first treated on the fifth and sixth days of illness received an initial dose of 10 and 20 g respectively, followed by 0.2 g every four hours for the next three to four days. In the patient given the largest doses blood levels of 40.5 µg per ml and urinary levels of 400 µg per ml were attained, in the other patients the maximum blood levels were 5 and 11.5 µg per ml and the urinary levels 100 and 220 µg per ml. The most noticeable result in all cases was the rapid fall in temperature while the rash remained unchanged. Results in the children were less easy to judge, since typhus in childhood is a comparatively mild disease. No toxic reactions due to the drug were observed. Though the best dosage can be determined only by much further study, it is suggested that the initial dose should be 40 mg per kg of body weight, followed by a total daily dosage of 35 mg per kg given in divided amounts at two-hourly intervals until obvious improvement in the general condition occurs. Thereafter 20 mg per kg of body weight should be given four-hourly till the thirteenth or fourteenth day after onset of the disease.

At present the effect of the drug on scrub typhus is being investigated in Malaya by an American team headed by Dr J E Smadel, who is working in collaboration with Dr Lewthwaite and Dr Savoor at Kuala Lumpur. Preliminary results, which were announced at the International Congress of Tropical Medicine at Washington held in May of this year, are very encouraging. Twenty-five patients have so far received chloromycetin, and 12 patients from the same areas have been used as controls.

Among those treated none has died and no complications have developed. The duration of fever after the first dose averaged 31 hours and the whole febrile period 7.5 days. Among the untreated controls one died, and this patient and one other had serious complications, the mean duration of fever was 18.1 days. At first the same large doses were given as were thought to be necessary in louse-borne typhus, but gradually the dosage was reduced till only 6 g was administered in 24 hours to the last seven patients. The results, however, were equally good. Half the patients were nursed under "bush" conditions in the hospitals attached to rubber estates. Further studies on the results of chloromycetin in rickettsial diseases will be awaited with great interest, for rickettsiae are resistant not only to the older chemotherapeutic arsenicals and antimonials but also to the sulphonamides and penicillin. Recent investigations by Smith and his colleagues<sup>6</sup> have shown that, though yeasts, fungi, protozoa, and viruses other than those of the psittacosis-lymphogranuloma group are unaffected, chloromycetin is active against a number of Gram-positive and Gram-negative bacteria, particularly Friedlander's bacillus, *Bacterium coli*, *Salmonella typhi*, *S. paratyphi*, *Shigella paradysenteriae* and *Haemophilus pertussis*. It is moderately active against various strains of tubercle bacilli. Bartz<sup>7</sup> has recently isolated chloromycetin in crystalline form. Its stability in solution is greater than

that of penicillin and in the acid range greater than that of streptomycin. It can be heated to 100° C for five hours without loss of activity. The solubility of the pure product in water is rather low, only 2.5 mg per ml, but its solubility in pure propylene glycol is high. When given parenterally it causes considerable irritation, but as it is extremely active when taken by mouth this is not of great importance. Another antibiotic of the same type, aureomycin, has now been isolated, preliminary reports suggest that it, too, is active against rickettsiae.

## FORMATION OF ADRENALINE AND HYPERTENSION

It is not yet known how adrenaline is formed in the body, but information is steadily accumulating. The general conception of the breakdown of amino-acids in the body was that they first lost their amino group in the process of oxidative deamination. In 1938 Holtz, Heise, and Ludtke<sup>1</sup> found an enzyme in various tissues capable of removing the -COOH group from dihydroxyphenylalanine (dopa), and they suggested that such an enzyme might play a part in the general breakdown of amino-acids, which only lost the amine group after decarboxylation. Blaschko<sup>2</sup> showed however, that the enzyme discovered by Holtz and his colleagues was specific for dopa, and other amino-acids were not decarboxylated, thus the process was evidently not a general one. The question then arose why dopa decarboxylase should exist, and Blaschko<sup>3</sup> suggested that it was probably concerned in the formation of adrenaline from tyrosine. The first change might be the introduction of a second phenolic hydroxyl group into the tyrosine molecule, thus forming dopa. Decarboxylation would then give hydroxytyramine, though whether the introduction of an -OH group into the side chain occurred before or after this decarboxylation there was at that time no means of knowing. Blaschko, however, showed that N-methyl dopa was not decarboxylated, and concluded that the primary amine noradrenaline must be formed as a preliminary to the formation of adrenaline itself.

The next step followed Holtz and Credner's<sup>4</sup> important observation that when dopa was given by intravenous injection or by mouth to rabbits a pressor substance appeared in the urine which they were able to identify chemically as hydroxytyramine. Thus they produced evidence of the normal activity in the body of the dopa decarboxylase. In the course of further work, Holtz, Credner, and Kronenberg<sup>5</sup> have shown that in normal urine there are pressor substances which are set free after acid hydrolysis, and they have produced pharmacological evidence which strongly suggests that these are a mixture of hydroxytyramine, noradrenaline, and adrenaline. They think that these substances may be produced in excess in the process of adrenaline formation, and that the body then gets rid of them in inactive forms which are excreted in the urine. They call the mixture urosympathin. They find that the amount

of these substances in the urine is increased in healthy individuals after strenuous exercise, and also in patients suffering from essential hypertension. In normal individuals the amount of urosympathin excreted in 24 hours is equivalent to 2-3 mg of hydroxytyramine, or to 0.1-0.15 mg of adrenaline. In essential hypertension it is equivalent to 8 mg of hydroxytyramine.

In a further paper Holtz and Credner<sup>6</sup> point out that renal ischaemia, by reducing the oxygen supply, will inactivate another enzyme which probably plays a part in removing substances like hydroxytyramine, which may be formed in excess. This is the enzyme amine oxidase, which converts hydroxytyramine to dihydroxyphenylacetaldehyde. The inactivation of amine oxidase will raise the amount of pressor amines in the blood. Loss of excretory power may have the same effect. Holtz and Credner administered 50 mg of L-dopa intravenously to 14 patients with nephritis and high blood pressure and also to 8 healthy subjects, they tested the urine excreted in the following 2-4 hours for the presence of hydroxytyramine by its effect on the blood pressure of the cat. They found little or no hydroxytyramine in the urine of the patients with nephritis and high blood pressure, but considerable amounts in that of the normal subjects. They demonstrated that the absence of hydroxytyramine in the patients' urine was not due to failure to convert the dopa to hydroxytyramine, for they found no dopa in the urine when they tested it for the total amount of polyphenol compounds. Thus renal ischaemia may lead to over-production of pressor amines by inactivation of amine oxidase and also to their retention in the blood. It should be made clear that these observations are considered by the authors to represent a subsidiary cause of hypertension, of less importance than the action of renin on hypertensinogen.

It has been shown by Blaschko, Holton, and Sloane Stanley<sup>7</sup> that in the formation of adrenaline the introduction of the -OH group into the side chain must follow decarboxylation, since they have found that the carboxylic acid of noradrenaline is not decarboxylated in animal tissues. This agrees with Holtz's evidence that dopa gives rise in the body to hydroxytyramine. Finally, Holton's<sup>8</sup> recent observation that a suprarenal medullary tumour, taken from a patient who suffered from temporary crises of hypertension, contained about twice as much noradrenaline as adrenaline supports the view that the last stage of adrenaline formation is the N-methylation of noradrenaline.

## END OF RADIUM COMMISSION

The affairs of the National Radium Trust and the Radium Commission are being wound up as a result of the coming into force of the National Health Act. The two bodies were established by royal charter issued under letters patent of July 25, 1929. The functions of the Trust were primarily to augment the supply of radium, and later, by supplemental charter, other radiotherapeutic apparatus, for use "in relation to the treatment of the sick in Great Britain" and for "the advancement of knowledge of the best methods of rendering such treatment." The main duty of the Commission was "to make arrangements for the proper custody, equitable distribution, and full use of the radium of the Trust with the object of promoting the

treatment of the sick and to make such arrangements for the supply on loan of the radium as are necessary"

When the Commission began work it was generally admitted that radium treatment in this country had not attained the standard then reached by such centres as the Fondation Curie and the Radiumhemmet. During the last nineteen years, however, some of the National (University) Radium Centres set up by the Commission have achieved a reputation equal to the best anywhere in the world. At the same time the standard of radiotherapy in general has been raised by the policy of centralization pursued by the Commission. Hospitals with small radiotherapy departments have been advised to make agreements with a National Centre for the treatment of their patients, and the formation of small independent centres has been consistently discouraged. The cordial relations which exist between the Commission and the staff of treatment centres have been fostered by personal visits, and the Commission has built up a reputation for disinterested service and unbiased advice which has been of the greatest value in the treatment of cancer in this country.

The present health organization requires that the work hitherto done by the Trust and the Commission shall in future be undertaken partly by a Ministry of Health committee and partly by the regional hospital boards. It is deemed advisable therefore that the radium and other radioactive substances, apparatus, appliances, funds, and property belonging to the Trust and the Commission shall be dealt with by vesting them in the Minister of Health or the Secretary of State for Scotland. The royal charter and the three supplemental charters are to be surrendered.

### SIXTY YEARS OF MEDICAL DEFENCE

Contrasted with the efficiency, stability, financial security—in a word, the success—of the three medical defence organizations as we know them to-day, it is surprising how fumbling was the approach to the problem only a little over sixty years ago. This history<sup>1</sup> of the Medical Defence Union, the pioneer society, by the secretary, Dr Robert Forbes, shows that the early steps were faltering indeed, in fact, two or three times in the first three years the project seemed likely to come to grief. Curiously enough, the initiators of it were laymen, not members of our profession, though that is not to say that the early troubles were due to this cause. Dr Forbes does well to recall, what few now remember, that the conception of a medical defence union arose out of a gross miscarriage of justice, recognized as such by the Home Secretary later on—namely the conviction of a medical man who was sentenced to two years' imprisonment on a charge of attempted rape resting solely on the evidence of an insane person. About the same time two partners had to spend £1,000 in clearing themselves of an unfounded charge of negligence in a diphtheria case. These two cases aroused the profession, and the Medical Defence Union was the result. Two other cases (both mentioned by Dr Forbes) had stimulating effects on the membership. The first of these was the celebrated Harnett case, where an ex-certified farmer brought an action for false imprisonment and was awarded fantastic damages, afterwards cancelled by a successful appeal, and the other was that of a country practitioner cast in heavy damages over a fractured femur, who would, so most people thought, have been exonerated if his defence had been conducted by a defence society. The *Lancet* raised a subscription to pay his expenses, but the editor afterwards announced that, since every practitioner could cover himself by join-

ing a defence society, on no future occasion would he repeat his action. Probably those to whom the young Union owed the most were Lawson Tait and Victor Horsley, both men of domineering personality as well as brilliant professional achievement—and both difficult to work with, of their successors Sir Herbert Waterhouse and Eric Pearce Gould have been the most notable, men as like able as the other two were the opposite. Considering that the election of Council members, theoretically a very democratic affair (as was to be expected in a constitution sponsored by Horsley), is in practice very largely oligarchic, it speaks well for the conscientiousness of successive Councils that nepotism has been conspicuously absent, there seems to be but one case where a son has succeeded a father (and in that instance greatly to the Union's advantage), though three brothers-in-law did also at various times serve as members. Dr Forbes handles tactfully the secession which more than fifty years ago resulted in the formation of a rival organization, now the Medical Protection Society. This whole brochure is eminently readable and interesting throughout, it is to be issued to every member of the Union, now and for some few years to come. Nothing but good can come of the publication of this valuable history, which reflects credit both on the author and on the august society whose secretary he is.

### LOCATION OF DISK LESIONS

Two difficulties have complicated the diagnosis and treatment of intervertebral disk lesions, the way in which symptoms are produced is not exactly known, and common variations in the lumbar plexus hinder accurate location of lesions by clinical neurology. Herniation of the nucleus pulposus may be regarded initially as a joint lesion. As such it can cause painful spasm in the lumbar muscles, postural changes, and secondary stresses in neighbouring ligaments. Removal of the displaced disk cannot restore the joint to normal, and this may explain the persistence of symptoms such as low backache after apparently successful operation. It may be that this joint derangement can itself give rise to deep referred pain throughout the corresponding sclerotome in the leg, even in the early stages before nerve roots are involved or localizing neurological signs develop. The experimental and operative studies of Falconer, McGeorge, and Begg,<sup>1</sup> however, show that severe limb pain in disk prolapse is mainly due to impingement of the displaced disk upon a nerve root. It is probable that the pain is produced by angulation and compression of the nerve root rather than by simple stretching. During laminectomy such distortion of the nerve over the protruded disk could be clearly seen when the straight leg was raised to an angle which normally induced limb pain. In patients who recovered after conservative treatment Falconer and his colleagues demonstrated by contrast myelography that the protrusion persisted unchanged. They therefore attributed recovery to spontaneous lengthening of the nerve trunk such as has been observed experimentally in animals, an observation which should encourage those who believe in persistence with conservative methods.

In the lumbar region lateral protrusion of the disk tends to involve the spinal root corresponding to the next segment caudally. Thus, a lesion at the level of the lumbo sacral joint affects the first sacral nerve, with production of deep pain throughout this sclerotome, the correspondence of which to the course of the sciatic nerve formerly gave rise to the belief that the syndrome was due to sciatic

neuritis Severe deep pain, muscle spasm, and backache are the dominant symptoms, but on careful questioning a patient will often describe a tingling, "pins-and-needles" sensation, alternating with periods of numbness and felt in the dermatome of the affected root. In such cases it is frequently possible to find small areas of impaired skin sensation. The similarity of these signs to those produced by experimental nerve compression suggests that they result from intermittent direct pressure on the nerve.

Keegan,<sup>2</sup> who has collected an imposing series of cases of disk prolapse confirmed in many cases by operation, uses the discovery of such hypoalgesic areas of skin to locate disk protrusions. He rejects the view that impairment of sensation does not follow lesions involving a single root, and he does not accept the acknowledged variability of the lumbar plexus as a serious difficulty. His anatomical studies indicate that "there is no change of position of the nerve roots with addition or reduction of lumbar vertebrae in man if the vertebrae are counted in numerical sequence and not by an arbitrary lumbar series defined by a quite variable first sacral segment and last rib." Further he asserts that the separation or fusion into plexuses is a secondary arrangement which does not alter the ultimate root distribution to the skin. He therefore claims to be able to locate the level of a disk lesion by reference to the dermatome charts constructed on the basis of his observations. Anatomists in general may not accept these views, but the chief criticism of this approach is that it neglects the factor of ascending oedema, which may involve several roots and, in the cervical region, the cord itself. Nevertheless Keegan is right to stress the importance of accurate clinical assessment of each case, and his work should discourage immediate resort to laminectomy following a typical history and a cursory neurological examination.

### INCLUSION BODIES OF THE ERYTHROCYTE

The eponymous inclusion bodies of the erythrocyte make a formidable list. To those of Maragliano, Howell, Jolly, Cabot, Isaacs, Heinz, and Ehrlich have recently been added the Pappenheimer bodies, and a reawakening of interest in the whole subject of erythrocyte inclusions is now evident. In 1941 Gruneberg,<sup>1</sup> using the prussian-blue reaction, had found siderotic granules in the erythrocytes of man, the rat, and the "curly tailed" mouse. He was later able to demonstrate these siderocytes in increased numbers after splenectomy and in cases of chronic uraemia.<sup>2</sup> Case,<sup>3</sup> employing a more delicate staining method with  $\alpha\alpha'$  dipyrindyl and potassium thiocyanate, showed that siderocytosis was related to haemolysis, though not to reticulocytosis. Case<sup>4</sup> and Granick<sup>5</sup> both believed siderocytes to be ageing corpuscles, but Gruneberg regarded their appearance as evidence of abnormal iron metabolism, and suggested that the siderotic material contained iron which had not been used for haemoglobin synthesis.

In 1945 Pappenheimer, Thompson, Parker, and Smith<sup>6</sup> reported another form of erythrocyte inclusion body which they saw in three cases of unexplained haemolytic anaemia following splenectomy. There were as many as 20 of these coccoid or rod-shaped bodies within a single erythrocyte. They gave a positive iron-reaction but did not stain by Feulgen's method. The authors concluded that although they could not be identified with any known parasite they might be of such nature, or they might be identical with

Gruneberg's siderotic granules. The problem of these Pappenheimer bodies has been studied by McFadzean and Davis.<sup>7</sup> They found them in a variety of haemopoietic disorders, but only in small numbers, except in acquired haemolytic anaemia. In eight patients with this disease Pappenheimer bodies were found in the peripheral blood and in the sternal marrow. Before splenectomy they tended to be scanty in the former and numerous in the latter. After splenectomy the number of affected erythrocytes in the peripheral blood rose sharply, in one instance from 3% to 88%, and in another from 11% to 82%. McFadzean and Davis believe that Pappenheimer bodies appear as a consequence of abnormal haemoglobin synthesis. From their observations of the flooding of the peripheral blood after splenectomy with cells containing these bodies they suggest that depraved erythropoiesis, resulting in cells doomed to early elimination by the spleen, may be the cause of haemolytic anaemia of this type. They are convinced that the siderotic granules of Gruneberg are different from the Pappenheimer bodies, and point out that Case regarded the former as a sign of age in a corpuscle, while the latter could be seen in reticulocytes and even in the nucleated precursors of erythrocytes. They have collected some evidence which suggests that the granules of basophilic stippling due to lead poisoning are similar to Pappenheimer bodies.

Less common, but with a longer history, are the Heinz-Ehrlich bodies first seen by Heinz<sup>8</sup> in 1890 in the erythrocytes of rabbits poisoned with phenylhydrazine. They stain poorly with Romanowsky stains, but readily by supravital methods, they give no iron-reaction. From time to time there have been reports of patients with anaemia whose erythrocytes contained these bodies. Fertman and Doan<sup>9</sup> have recently recorded the case of a 71-year-old physician who had taken 500 quarter-grain tablets of erythrol tetranitrate during the course of a year for angina pectoris and was admitted to hospital with a haemolytic anaemia. Inclusion bodies of the Heinz-Ehrlich type were found in up to 16% of his erythrocytes. The anaemia was unrelieved by iron, liver, or blood transfusions. Heinz-Ehrlich bodies, unlike the Pappenheimer bodies, were rarely seen in erythroblasts, this conforms with Figges's<sup>10</sup> view that the former are probably globules of denatured haemoglobin. His opinion is endorsed by Gajdos and Tiprež,<sup>11</sup> who have shown that their appearance depends on the sequestration of the porphyrin ring in haemoglobin to form verdohaemochromogen, an early step in the degradation to bilirubin.

Although these three types of inclusion do not appear to be identical, they are all commonly associated with a haemolytic anaemia and indicate some disturbance of haemoglobin metabolism. The Pappenheimer body signifies defective haemoglobin synthesis, the Heinz-Ehrlich body precocious degradation, while the implication of the siderotic granules of Gruneberg is as yet uncertain. All are found in pathological erythrocytes, and the segregation and destruction of such cells by the spleen may be the basis of the haemolytic anaemia which marks their presence.

### THE HALF-YEARLY INDEXES

The half-yearly indexes to Vol. II of the *Journal* and the *Supplement* for 1947 have been printed. They will, however, not be issued with all copies of the *Journal* but only to those readers who ask for them. Any member or subscriber who wishes to have one or both of the indexes can obtain what he wants, post free, by sending a postcard to the Accountant, B.M.A. House, Tavistock Square, London, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

## MENTAL HYGIENE AND WORLD PEACE

### Opening of International Assembly

Following the two specialist international conferences, the International Conference on Mental Hygiene was opened at Westminster Central Hall on Monday, Aug 16. About fifty nations were again represented among the delegates, and the opening ceremony was attended by leading representatives of medicine, public health, psychological science, and social administration. A message was read from the King in which he expressed himself as confident that the Conference and the work done in preparation for it would "contribute to a better understanding of troubled communities and a convalescent world." In a loyal reply it was stated "Your Majesty's demonstration of what happy family life can mean to mental health is in itself a source of inspiration."

Dr J R REES, President of the Conference, referred to the vast amount of preparatory work which had been carried out. Discussion groups had been working in 27 countries over a period of many months, and for a fortnight before the Conference met a Preparatory Commission had been preparing a statement as a basis for consideration. Dr Rees wondered whether there were many other instances in which a document covering so large a field had been produced by agreement between scientists and sociologists of ten countries and of eight different professions.

VISCOUNT ADDISON, Lord Privy Seal, who welcomed the Conference in the absence on holiday of the Minister of Health, recalled that when it was decided thirty years ago to set up a Ministry the conception of health which was accepted was the same as that which now appeared in the constitution of the World Health Organization, namely, "Health is a state of complete physical, mental, and social wellbeing, and not simply the absence of disease or infirmity." Harassing conditions of life, Lord Addison continued, by imposing continual anxiety on men and women, especially women in the home, provoked many of the conditions which led to physical or mental ill-health, but at the same time he had come across a large number of discontented people who were not in the worldly sense hard up, and he had often wondered what caused their anxieties. He thought that first and foremost it was because they lacked the right attitude to occupation. A satisfactory occupation had much to do with a state of mental restfulness. One of the biggest questions before the world to-day was whether people were prepared to face the responsibility for the vast forces which physical science had put into their hands. Wars began in the minds of men, and it was in the minds of men that the defences of peace must be constructed.

Mr R A BUTLER M P, president of the National Association for Mental Health, joined in the welcome. What agencies, he asked, were more important than those which contributed to the expansion of the social sciences, and in particular attempted to explore and chart the puzzling wilderness of the brain? He said "wilderness" because he was convinced that there was relatively more unknown territory to explore in the mind of man than remained undiscovered on the terrestrial globe. A world-famous brain-specialist in Canada recently remarked to him that there were ahead a hundred years or more of patient exploration of the normally unused recesses of the brain. Here was work for the Columbus or Magellan in their ranks. Mental health investigation called for team work and pooling of ideas. He had great hopes of the results of the present gathering because it represented every profession concerned with mental health, he trusted that its conclusions would be a spur and stimulus to mental-health workers all over the world and through them to their associates, the administrators, diplomats, and politicians.

To emphasize the world-wide character of the Conference, brief messages were given by representatives of six continents. For North America Dr FREMONT-SMITH, vice-president for the United States of the International Committee for Mental Hygiene, said that, just as physicists, chemists, engineers, and others needed to collaborate in the work on atomic energy, so must they, the specialists in individual and group behaviour, join forces to construct a different kind of cyclotron, one which would use the powerful rays of human intelligence to untap

the energies of good will and co-operative effort in the heart of man.

For South America Professor HENRIQUES ROXO, of the Psychiatric Clinic in the University of Brazil, said that it was for the Conference to interpret the reasons for what was now occurring in the world. If there should be mental illness it must do its best to cure it, if only symptoms of maladjustment, it must indicate ways of reconditioning. For Asia Dr K R MASANI, president of the Indian Council for Mental Hygiene, suggested that some clear cut recommendations should go from the Conference to the World Health Organization and to Unesco.

For Africa Dr LOUIS VAN SCHALKWIJK spoke of the social work proceeding in the Union of South Africa, a country which, he said, was mental health conscious. Dr HENRY MAUDSLEY of Melbourne, brought the greetings of Australasia, and, finally, for Europe, Dr ANDRE REPOND of the Swiss National Committee for Mental Hygiene, drew an analogy from the way in which the people in his own country dealt with avalanches, not by erecting barriers at the foot of the mountain, but at the top of the slope where the snow first settled. It was in the realm of ideas before they became action that catastrophe could be prevented.

### The Conference and the World Health Organization

The good wishes of the first World Health Assembly meeting in Geneva were brought by Dr G BROCK CHISHOLM, director-general of WHO. He pointed out that Governments in their international relationships could not be much more tolerant, co-operative, or helpful than the mass of the people who put them in power. Not too much was to be expected from Governments until people everywhere became more world-minded and emotionally capable of functioning as world citizens. He hoped that a World Federation for Mental Health would play a significant part in helping the world to learn to live in peace.

Dr ARVID BRODESLIN, representing Unesco, mentioned the co-operation between his organization and specialists in mental health, including national and international organizations.

These complimentary proceedings over, the Conference settled down to its discussions, the theme for the week being mental health and world citizenship. Professor RENE SAND, professor of social medicine, University of Brussels, took the chair during the first discussion, when problems of world citizenship and good group relations came forward. Professor Sand remarked that it was fitting to be meeting in the year which marked the centenary of the Public Health Act in England, and this was a welcome opportunity to acclaim Edwin Chadwick, Southwood Smith, and others to whom the passing of that Act was due. By a coincidence it was also a hundred years ago that the expression "social medicine" was coined by a French medical journalist, Jules Guérin, in the *Gazette Medicale de Paris*. It was also fitting to be meeting in historic Westminster, close to the Houses of Parliament, that substantial bulwark of freedom and progress, opposite the Abbey, the shrine of the men who had served both England and mankind and in the very hall in which the first assembly of United Nations had met.

A somewhat diffuse discussion was opened by Professor CARL BINGER, of Cornell, who spoke of the need for finding moral equivalents for war, and also the need to know more about the transmission of war fever, how the infection spread, and why it was no longer a localized outbreak but so quickly reached epidemic or global proportions. Delegates from Switzerland, France, Greece, Norway, Iran, and Czechoslovakia addressed the Conference, and Dr EDWARD GLOVER, who presided over this part of the meeting, summed up. He said that the work of the preparatory groups, although they had been functioning only for a year or so, had resulted in a nucleus organization in many countries, and had shown that everywhere there were people who were prepared to get down to the necessary committees on the subject of mental health. This work must be continued. He spoke of the need, particularly on this topic of world citizenship, of making use of the disciplined exercise of the imagination.

In the evening a reception was given by H M Government when Lord Addison received the guests.

## INTERNATIONAL CONGRESS ON MENTAL HEALTH

[Continued from page 396]

### Third Day

#### PSYCHIATRIC PROBLEMS IN EDUCATION

The morning session of Aug 13 was devoted to the topic of psychiatric problems in the educational sphere, and the chair was shared by Dr B BEHMAN (Egypt) and Dr S AHNSJO (Sweden). The subject was introduced by Dr JEANNE DECROLY (Belgium), who, while admitting that the school was in many instances a contributory cause of aggressive behaviour, considered that by careful attention to compatibilities as between teacher and pupil and between pupils themselves the school atmosphere could create an environment favourable to the improvement of even the gravest forms of aggression.

Dr GORDON STEPHENS, out of his experience as psychiatric consultant to the Winnipeg Child Guidance Clinic, set out a number of school influences which imposed undue restrictions upon healthy expression in the majority of children. One of these was a curriculum over stuffed with rigid, unrealistic subjects, tolerable only to an abnormally submissive child. Frustrations arising in the class-room with more than thirty children and an average teacher were obvious. Another severe source of frustration for at least half the average class was the measurement of academic achievement by examinations. Then there was the frustration due to restricted outlets for recreation, which produced irritability, restlessness, and impaired performance. He included among his unfortunate influences the preponderance of female teachers. In the Winnipeg school system there were three times as many female teachers as male, and several thousand boys had no male teacher until they were twelve or thirteen. Many of the women teachers, though by no means all, were a source of frustration to their pupils. But the most traumatic and crucial frustration which the child encountered in his school life was poor teacher-pupil relationship. "Too many teachers seem to choose their profession as an escape from the aggressive and more mature adult environment," Dr Stephens added that the same was said about some psychiatrists and social workers.

Finally Dr LUCIEN BOVER (Switzerland) spoke of the complementary (and in both cases limited) tasks of the physician and the educationist, the latter taking over at the point where the former left off. He begged the Congress to pass a recommendation that the training of doctors should include a training in experimental medical psychology and child psychiatry, that the training of educators should include training in psychopathology in so far as it related to the child and the adolescent, that medico-pedagogic services should be created to help in the diagnosis, therapeutics, and prophylaxis of the troubles in the development of the child and the adolescent, and that a body of psychiatrists should be attached to the schools in the same way as school nurses.

In some general discussion Dr LAURETTA BENDER (United States) described work among problem children in New York who had been brought up in institutions and deprived of the mother relationship so that they had become virtually ineducable, unable to identify with their teachers and school-fellows in a group programme. Dr ANTOINE PIERSON (Morocco) reminded the Congress of children in North Africa, products of an ancient civilization, in which the ordinary father-mother-child relationship did not hold, the child finding himself in a family of many mothers, and receiving no particular individual attention. The idea of personality in such children emerged much later. Mrs LLOYD NOAD (Australia) suggested that the nursery school was the place in which 'to begin to outlaw war'. Dr ALICE-MARIE LAPORTE (Belgium) described the lot of many Continental children who during the occupation had lived in a state of alternate exhilaration and fear which was highly detrimental. Various factors, such as insufficient housing and the black market, had contributed to further character degeneration. Moreover, teachers were apt to be neurotic, they were overworked, and owing to war circumstances many of them remained unmarried, so that their affective life was entirely dependent on the children. Every school should be provided with a trained psychiatric social worker. Dr G VAN LOON (Holland) gave an account

of Dutch children who had lived in the worst imaginable conditions during the war. In a group of 540 such children, however who had been orphaned and placed with foster parents, 90% got on well with them, and the frequency of aggressive and anxiety phenomena was only about 5%. The discussion was concluded by Dr RENE DELLAERT (Belgium) and Dr ANNA MARSHEN (United States), the latter remarking that psychologists too often dwelt in an ivory tower, and, seeing the problem of each child one by one in the luxury of the private interview, did not appreciate the influence of its surroundings upon the child's behaviour pattern.

#### COLLECTIVE GUILT

The subject of guilt, which had already occupied two sessions, was carried to a higher level in a discussion on collective guilt. The distinguished American anthropologist, MARGARET MEAD, introduced the subject from the standpoint of a comparative study of cultures. She referred in particular to the culture of the North American Indians and the less-known cultures of South America, which were based on shame as a sanction—that is to say, the child internalized not fear of loss of love or of punishment from its parents, but fear of disapproval by the whole of its group. In later life the individual conformed in shame and the shame remained an external sanction in which the chief effort was to avoid exposure to open ridicule and opprobrium. She outlined some other types of sanctions which were found in different cultures of the world and on the basis of comparative cultural data she came to the conclusion that the capacity to experience guilt as a dominant psychological mechanism was a human capacity which might be either developed or neglected by any given society and could not therefore be regarded as either universal or necessary, however desirable it might be found in terms of contemporary ethics.

Dr POUL BJERRE (Sweden) contested the proposition that aggression, like sexuality, was an instinct inherent in the nature of mankind. If it were the said, war could never be abolished. All talk of sublimation would be empty talk, for no instinct could be satisfied except directly through its own channels. One might divert the attention from hunger by reading poetry but it was impossible to satisfy thereby the need for food. Sooner or later, if aggression was an instinct, it would find an outlet in war. But in his view it was impossible to regard aggression as an elementary instinct: it was a reaction to inhibitions, neither more nor less.

Dr KRUGERS-JANZEN (Holland) read a paper in which he compared collective guilt with individual guilt from the standpoint of developed psychology, and Dr H V DICKS (Great Britain) entered upon an interesting analysis of the culture of pre-war Germany, with the authority of the father-figure resulting in a rigidly ordered society with a high degree of subordination linked to dread of social change. A highly theoretical discussion was continued by Dr KATE FRANKENTHAL (USA), Professor G BOSCHE (Italy), Dr CLIFFORD SCOTT (Great Britain), Dr F GREWEL (Holland), and Dr CHOISI-CLOUZET (France).

### Fourth Day

#### THE CHILD DELINQUENT

The final session of the International Congress on Child Psychiatry, on the morning of Aug 14, considered the problem of the child delinquent. The chairmen were Dr CARL FRANKENSTEIN (Palestine) and Dr KATA LEVI (Hungary). Three opening papers were read. Professor DE SANCTIS (Rome) expressed the point of view of the Italian school, and emphasized the importance of religious education. There was no cleavage between medicine and religion which could not be bridged. Dr JEAN DUBLINIAU (Paris) discussed the framework of re-education and Dr G E GARDNER (Boston, USA) the expressions of sexual instinct in childhood which led to sex delinquency, with particular reference to the role of aggression in such acts.

Dr J D W PEARCE (Great Britain) thought that too little attention had been paid in discussions on this subject to individual differences in native endowment as between one individual and another. Dr GEORGE HEUYER (France) astonished the Conference by calling for the abolition of all juvenile courts and judges. Delinquent children, he said, should not be

dependent upon the administration of justice but should be dealt with by some other department which did not import a legal or penitentiary aspect. Dr FRANK BODMAN (Great Britain) mentioned the factor of social backwardness or defectiveness, as distinct from mental defect, as important to bear in mind in these cases. Dr KLINSBERG (U.S.A.), in pointing out that criminality or delinquency varied from community to community and from period to period, amused the conference by the story of a man in the prohibition era who offended against the law, but before his trial the law was altered. He was, however, fined for breaking the law as it had then stood, and promptly entered the previously illegal employment of brewing in order to pay the fine. Dr G. K. STURUP (Denmark) spoke of the desirability that communities in which aggressive children were brought up should be small. It was hopeless to make a home out of a group of thirty children. Group co-operation in adults as well as in children was impossible above a certain number. Others who took part in the discussion were Dr KAISA LEPPÖ (Finland), Dr J. ROUDINESCO (France), Dr LUSCIONI (Algeria), and Dr O. FLEISCHMANN (Austria).

This brought to a close the International Conference on Child Psychiatry, and Dr J. R. REES, the president, announced that it had been decided that the Comité International de Psychiatrie Infantile should be reconstituted as the International Association, with one representative from each country on its council. Dr Frederick Allen, of Philadelphia, had been elected the first president of the new body, and an invitation to hold the next International Conference in Philadelphia had been received.

### ADVANCES IN GROUP THERAPY

The closing session of the International Conference on Medical Psychotherapy was concerned with advances in group and individual treatment. Professor O. KAUDERS (Vienna) and, later, Dr W. REES THOMAS presided. Criticism of the group method was made by Dr C. A. MEIER (Zurich). In Switzerland nobody was practising anything like group therapy, but then Switzerland had not had to cope with war neuroses and psychoses. Group therapy was said to be gaining ground in England and America—a disconcerting thought, for it looked as if it was becoming a fashion. If it had arisen only as a war necessity it should by now have been losing ground. It was a makeshift substitute for individual therapy when the latter was too expensive in money for the patient and in time for the overworked analyst. Grouping was a collective situation, it sacrificed the personal *vis-à-vis*, it could be only palliative and in the long run create a vacuum. One effect of group therapy was claimed as an advantage—namely, that it diminished the resistance of the patient—but this, Dr Meier argued, was no real gain, for resistance might be a protective system against complete breakdown.

"Brief psychotherapy" was described by Dr W. B. TERHUNE (U.S.A.). This, he said, was a practical form of individual psychotherapy which chose the best methods from all schools. Most of the patients so treated were fundamentally and permanently helped. Two years was the minimum time required for the training of a psychiatrist in the basic technique of brief intensive psychotherapy. The method employed the recognized processes of abreaction. It was largely dependent for its results on quick, strong, and successful transference. The patient was subjected to the treatment for from three to eight weeks. It could be used successfully in an out-patient clinic.

Dr W. R. BION followed with an exposition of group therapy as practised at the Tavistock Clinic. In psycho-analysis the most important condition was "one patient, one doctor." He had had it in mind, however, to elaborate a form of treatment for the proper carrying out of which a group would be as essential as the intimate relationship between two individuals in psycho-analysis, in other words, any form of treatment in which the psychiatrist felt that he had a group of patients *faute de mieux* was bad treatment, whereas any form of treatment, supposing it could be worked out, for which a group was essential would be good treatment. After describing his methods he said that, while most of the patients who had claimed to be better did not approach any standard he would have regarded as satisfactory in individual treatment, nevertheless there was an element of improvement which was stable and genuine.

Another exponent of American methods, Dr DANIEL BLAIN said that group therapy had been practised in America for many years, but there was a rapid expansion of the method during the war. At first it was considered purely a method of convenience in view of the shortage of psychiatric manpower, but now it was believed that there was something in it over and above individual psychotherapy, and that in its exercise just as much skill, though perhaps of a different kind, was required. The evidence that it produced results of value was subjective at present, but it was just as good as the evidence of most people reporting their work in individual psychiatry, because that also had not been submitted to any scientific valuation or objective control.

This and other recent developments in applied medical psychology were reviewed by Dr E. B. STRAUSS (London). Such methods had come about, he said, as the result of a long felt demand for effective short cuts in order to cope with the increasing number of patients who needed psychiatric help. The new methods included narco-analysis, abreactive psychotherapy, group therapy, and therapeutic social clubs. Although group psychotherapy originated in the United States, British psychiatrists had carried the application of the principles much further than was common in American practice. The form was most diffuse in the therapeutic social club and most compact in the closed analytical group. Many therapeutic social clubs had been started in Great Britain, both inside mental hospitals and in connexion with psychiatric out-patient departments. The group situation, with its opportunity of transference reactions, forced the patient out of his isolation by bringing him into vivid contact with the social situation and causing him to see his own anxieties and morbid ideas mirrored in other members of the group. Resistance was broken down and dynamic unconscious material more readily activated.

Two American psychiatrists spoke further on the subject. Dr JEROME FRANK said that in his clinic psychotics had been receiving group treatment only, neurotics received both group and individual treatment. The groups were small, ranging from five to ten members. Group therapy was a valuable adjunct to individual treatment, and for many patients it took its place. Dr S. R. SLAVSON pointed out that if one error was made in selecting a patient for the group there was no psychotherapy, but only confusion and exhaustion for the therapist. But, given the right selection, there was a large field for group treatment. The great thing was to choose patients who were similar not in their symptoms but in their psychodynamic syndrome. Psychiatrists had made the mistake of choosing patients on the basis of symptoms, whereas similar symptoms might derive from very different causes.

Dr JOHN RICKMAN (London) said that no doubt in some cases it was an advantage for treatment to be brief, but brevity in this field was not the way to knowledge. One price which could not be accelerated was the pace at which human problems could be understood. It led to sheer confusion to speak about brief therapy and group therapy as though they were the same thing.

Other speakers on this subject were Dr ANGELO (Italy), Dr C. JORGENSEN, who gave an account of group therapy as practised in the municipal hospital at Copenhagen, and Dr A. M. ALONSO (Venezuela). The final speaker was Dr KEMPER (Berlin), who described the experiences of a large clinic where psychiatric treatment of up to 150 hours in an individual case was given. The staff included followers of the Freudian theory, but representatives of other schools as well. He agreed that major analysis could not be replaced by any brief treatment. The decisive condition in brief therapy was the correct choice of patient. The method was justified in one case and not in another, it was neither a substitute for nor a branch of analysis.

The International Conference of Medical Psychotherapy closed with warm expressions of appreciation from the delegates from abroad for the work of British organizers.

On the intervening Sunday special services were held at St Paul's Cathedral and the Central Hall, Westminster, and at Westminster Cathedral there was a solemn High Mass for members of the Congress. At St Paul's the preacher was Dr Donegan, the Bishop Suffragan of New York, and Mr R. A. Butler, M.P., read the lesson.

## PSYCHOSOMATIC MEDICINE

### Widening Concepts

The meetings of the International Conference on Mental Hygiene, the third of the assemblies of the Mental Health Congress continued at Westminster during the whole of last week with eagerly sustained discussions on individual, family, and industrial relations. On two afternoons nine specialist meetings were held. At one of these, under the auspices of the Royal Medico-Psychological Association and the chairmanship of Dr W REES THOMAS a discussion took place on the widening concept of psychosomatic medicine.

This subject, in particular relation to public health, was introduced by Dr J L HALLIDAY who pointed out that the physical health of a nation could be assessed from its mortality rates, the incidence of infectious diseases, and so on, but for its social health it was necessary to know not only the occurrence of neurotic and psychotic manifestations but the fertility, the incidence of delinquency, and many other phenomena—economic, industrial, and cultural. Thus it was possible for the wartime paradox to occur, when the physical health of the population improved while its social health declined.

For the improvement of the psycho-social health of a community certain social patterns had to be altered. Dr Halliday mentioned some of the changes in social pattern which had occurred during the three years since the end of the war, and showed how in each instance there was a balancing of factors. There had been full employment, but along with that a certain rigidity in card-indexing and labelling of workers. There had been Government grants for higher education—an excellent policy, but its emphasis on the training of technicians tended to turn some universities into technical colleges. The advent of a State medical service would bring much social good, but also, if care were not taken, certain social evils—one being that creative ideas in the field of medicine might be discouraged and prevented. The nationalization of industries had taken place, but associated with it an increase in bureaucracy. The question was whether on balance these measures were lessening the causes of social sickness. The indices of psycho-social disorders which would give an answer were not available. There was, of course, the favourable employment index and a rise in the birth rate, but a rise in the birth rate had followed the earlier war and had proved to be transitory. One favourable figure was the post-war decline in the death rate from peptic ulcer which had risen steadily between the wars. The incidence of exophthalmic goitre and of diabetes was less, and the improvement in the latter disease was not wholly explainable by sugar rationing. Suicide, again, was declining. All this seemed to argue a loosening of obnoxious social pressure of some kind, but until there were adequate morbidity statistics such a conclusion should be accepted with reserve.

### The Social and Psychological Background

Dr ERIC WITTKOWER dealt with some common conditions from a psychosomatic point of view. It had been observed that patients with venereal diseases frequently came from broken homes. Of female patients in one recorded observation 80% had unresolved conflicts concerning their family. All observers agreed that delinquency and criminality were common in patients with VD. The all-round picture was that such patients were emotional and sexually and socially immature, though physically and mentally they might have reached full maturity. The evidence of immaturity was most striking in the habitually promiscuous. War experience had been instructive in revealing the background of venereal disease. The bond of marriage in newly wedded couples might not be strong enough to withstand the disuniting effect of long separation. Men in the Services lived in a regimented community abroad or in isolated posts, and boredom was conducive to promiscuity.

Turning to tuberculosis, Dr Wittkower said that many individuals who developed this disease seemed to have in common an inability to deal adequately with aggressive impulses and were prone for varying reasons and in different ways to turn these impulses against themselves. Illness and disablement in general had a regressive effect on the ill person, showing itself in hypochondriacal tendencies, surrender to despondency, and a

'blind, childlike faith in the powers, indeed the infallibility, of the doctor.

Generally speaking there was no justification for feeling guilty of being ill, but a person who felt guilty revealed by so doing that he was aware of an aggressive aim and purpose in his illness. Chronic illness almost invariably mobilized aggressiveness, finding expression in irritability and outbursts of temper. To many persons illness was equivalent to weakness and failure. Patients not infrequently felt ashamed of being ill, especially if the disease was one to which a stigma attached. The disproportionate emotional reaction to minor acts of kindness which was found quite commonly in the chronic sick could only be understood on the basis of assumption that they did not believe they deserved them.

Dr Wittkower also spoke of the emotional reactions attending loss of sight or the amputation of a limb. He said that the general belief that blinded persons were meek was mostly erroneous. Their dependence on sighted people and their need for affection compelled them to check aggressive traits or show them only in sarcastic wit and fantasy. Men who lost an arm had more severe emotional reactions than those who had had a leg amputated. There were various reasons for this, the arm being more important for social relations, self-expression and occupation, while its relative nearness to the heart made the loss of it seem a greater threat to life.

Dr J C AUERBACH (United States) urged that a halt should be called at the point where they could still speak of medicine, otherwise they would be "swallowing a bigger bite than they were able to digest." He thought that the term psychosomatic disease should be restricted to conditions in which the psychological disorder, occasioned perhaps by the disease or injury, itself reacted again upon the body. Dr G H DAY, speaking from his experience of pulmonary tuberculosis, said that many of the patients were subject to conflicts. If the conflict, whether external or internal, was resolved they got well, if the external conflict (inability to get on in the social setting) was insoluble they lapsed into chronic invalidism, and where there was an insoluble internal conflict the illness might well prove fatal.

Dr RONALD MARKILLIE asked about the connexion between responsiveness to emotional factors and proneness to catch infection in an epidemic. On the question of suicide he suggested that some people died not by actually taking their own lives but as the result of a depressive process similar to that which operated in the mind of the suicide so that though they might be expected to commit suicide they did not do so, and yet they destroyed themselves by the precipitation of some grave disorder.

### Family Problems and Psychological Disturbance

In the plenary session devoted to family problems the opener of the discussion was Dr P J REITER, president of the Danish Association for Mental Hygiene. The disorganization and disintegration of the family institution, he said, was demonstrated by the increasing number of divorces. He was not prepared to say that matrimony at any cost ought to be preserved. Divorce might be preferable to continuing disharmony. But the important thing was a systematic and careful education of young people to a better understanding of the emotional, personal and social aspects of matrimony. Another problem was "extra-matrimonial births." This was not to be solved merely by counteracting conventional prejudices against the unmarried mother. The psychological effect went deeper. The illegitimate child during adolescence would miss the father-figure, while the mother-figure was likely to be defective in certain ways—bitter, disillusioned, severe, over-critical, over-anxious. The only child, again, was missing to a high degree the normal social microcosm, and was specially exposed to difficulties in dealing with the Oedipus situation. Difficulties of a similar character arose in families in which the children were spaced out at very long intervals.

Dr LESLIE HOUSDEN urged that a real attempt should be made in all countries to raise the standard of parentcraft. We poured out treasure and effort in trying to restore mental health to one generation while our homes manufactured casualties for the next. The Ministry of Health had appointed an adviser in parentcraft—the first such appointment in this country, and he did not know of a similar one elsewhere.

The work of the Marriage Guidance Council was described by Dr EDWARD GRIFFITH. It co-operated harmoniously, he said, with churchmen, doctors, and educationists. The need for such work was obvious. Marriage disharmony was increasing in practically every country. Sex relationships before marriage were on the increase. One in four of all women who married for the first time was pregnant before marriage. The rates of illegitimacy, abortion, and venereal disease were going up. The 500 divorces in this country in 1900 had become, probably, 50,000 this year. The causes of all this were widespread—economic insecurity, materialism, the changing social pattern, combined with a lack of creative outlet and ignorance of the biological, psychological, and spiritual factors in personal relationships. The first cure for marriage disharmony lay in effective and widespread pre-marital education. Adequate marriage preparation would go far to remove frustration, fear, and anxiety, such as dominated so many marriages and destroyed family life.

The religious ideal was put forward by at least two speakers. The Rev ROBERT MORRIS (USA) mentioned that in a community church in Ohio, where particular care was taken in the nurture and instruction of young people in respect of sex and marriage, 643 men went into the armed Forces and not one of them was discharged on account of any neurotic or psycho-neurotic disorder. This result had been obtained by combining the principles of mental health with a wholesome faith. He also mentioned that this summer in the United States 145 theological students were taking a clinical course in hospitals in order to get to know people and their difficulties. Dr PATRICK MORAN (Eire) also emphasized the religious factor. There was no synthetic substitute, he said, for a wholesome family life.

#### Medical Leadership in Industrial Relations

The session of the Congress which was most sparsely attended was the one concerned with mental health in industry and industrial relations, and fewer papers had been contributed to the Preparatory Commissions on this subject than on the others. The discussion turned to a considerable extent upon the question of medical leadership in industry. Professor WILLIAM LINE who is professor of psychology at the University of Toronto, called upon medicine to show leadership in this field which hitherto it had found difficulty in giving. "Medicine is in danger—on the North American continent at least—of becoming or continuing as a vested interest that will hamstring us as much as would the Church or industry itself." There had always, of course, been the example of the general practitioner in taking individual well-being as an objective, and there had been exciting, though isolated, instances of medical leadership in public mental health. He recalled the dramatic change of medical leadership in the Canadian Army in 1941 associated with the appointment of Brock Chisholm, now director-general of the World Health Organization, as D G M S. Up to that point army medicine had followed the traditional pattern of wounds, sickness, and sanitation. Immediately, however, there began to emerge a series of general staff directives to the effect that illiteracy in a culture demanding literacy was a health matter, that routine as a dominant condition of employment was a concern of the medical officer, as were selection and induction, and so on through the whole gamut of service morale. The whole conception of social ill-health was medical in origin, at least at the technical level. "The great virtue in medicine lies in its professional tradition. To the doctor there is no distinction between manager and worker. Neither can the doctor's policy or technique be prescribed by anyone other than his professional associates, whom he represents at all times."

All mental health work in industry, declared Professor Line, should be sponsored by professional medicine. The exact method of sponsorship would have to be determined locally, but the sanctions would be those of the ultimate professional medical authorities. If the present Congress contented itself with blessing lay groups, however politically or economically dominant they might be at the present time, and failed to meet the challenge of universal professional health sponsorship, it would have failed dismally. Work and industry were public health matters of first priority.

Dr G R HARGREAVES raised the delicate point of the doctor's own industrial relations. Psychiatric hospitals, he said,

displayed an archaic, autocratic pattern of working groups such as no longer existed in industry. The professional group was detached from other workers who made the wheels go round, so that very few doctors knew the name of the nurse who worked in their ward or the name of the liftman who took them up to that floor. Yet medical men, like others, were in a working group which could not be separated from the rest of society. This speaker dissented from Professor Line in his insistence that public health leadership should necessarily be undertaken by doctors, and he was doubtful whether social science and research in industry should necessarily be under medical control. One of the most distinguished professors of public health was an engineer, and the adviser on nutrition policy to the Ministry of Food was a biochemist. It would be foolish to believe that doctors were the only people to make a leading contribution in the field of health. At any moment, as occasion served, one or other member of the team—psychiatrist, sociologist, educationist—might take the lead. Dr ELLIOTT JACQUES spoke somewhat to the same effect. The problem of human relations in industry applied also to those who worked in the medical and social sciences. Could it be said that in scientific societies, in mental and general hospitals, in university departments, human relations concerning medical and other staffs were always modelled on the pattern they would like to see adopted in industry?

Dutch, Finnish, and French delegates took part in the discussion. Dr P M TURQUET made the useful point in an international assembly that many of the English terms used had no exact equivalent in other languages, and if they were to become world citizens they should use translatable terms. He knew of no French equivalent for "nervous breakdown," "frustration," "pilot study," or the statistical term "scatter" and similarly certain French and German terms appeared to have no English equivalent.

#### Concluding Sessions

The closing sessions of the Congress were devoted to the subject of planning for mental health organization, training, and propaganda. Dr T FERGUSON RODGER, professor of psychiatry, University of Glasgow, and Dr A QUERIDO, director of department of mental hygiene, Amsterdam, presented detailed surveys of present mental health services, with indications for the directions in which they should be extended. Dr J KEARNEY (Dublin) described the operation of the Irish Mental Treatment Act, 1945, whereby no judicial authority intervenes in the process of the reception of persons of unsound mind or temporary patients into a mental hospital. The procedure is entirely medical, and the Act has done much to remove the stigma so long associated with mental disease. Col A A W PETRIE gave some indication of the problem in the LCC area, where 34,000 people are dealt with under the Mental Treatment and Mental Deficiency Acts. In general discussion the complaint was made that there was almost no reference to the role of the teacher in the documents before the Congress, and that none of the national delegations included a practising teacher.

At a meeting held under the auspices of the National Association for Mental Health Dr DORIS ODLUM and others spoke on the various methods of bringing the principles of mental health home to the public—the appeal, on the one hand, to specialist groups such as educationists, magistrates, and industrialists, and, on the other hand, to a wider public, to whom the matter must be presented in some concrete way. The Royal College of Nursing arranged a special session for nurses, at which speakers from the United States, South Africa, and this country discussed recent trends in mental nursing. The Royal Medical Psychological Association continued on a second day its discussion on the widening conception of psychosomatic medicine. Dr H CRICHTON-MILLER suggested that there was a tendency among psychiatrists on both sides of the Atlantic to reserve their diagnostic and therapeutic activities for only one side of this problem—namely, the influence of the mind upon the body. If they were to be balanced in their treatment of both neuroses and psychoses they must not neglect the influence of the body on the mind. In Westminster School Hall a playlet entitled "The Universal Heckler," produced by Miss OLGA DRUCE (USA), was demonstrated as a method of public education on the topic of anxiety.

### World Federation for Mental Health

At the final meeting of the Congress Dr J R REES announced that a World Federation for Mental Health had been constituted during the week, with an executive committee consisting of twelve members from almost as many countries. The members of the Federation would be not individuals or nations but the professional societies in the various countries interested in this subject, and it was hoped in this way to secure a real co-operation of all bodies—educationalists, psychologists, anthropologists, sociologists, and psychiatrists. The Federation would eventually, it was hoped, have an office in Geneva. Its annual assemblies would take place in different countries, and there would be no limit to the number of observers who could attend. Dr Rees himself was elected the first President of the organization, with Dr André Repond as vice-president and Dr Kenneth Soddy as secretary.

Dr JULIAN HUXLEY said with what pleasure he had heard of the formation of this permanent organization. The Executive Board of Unesco, at its last meeting, anticipating that the Federation would be formed, had recommended that it should be accorded consultative status so that it could be represented at Unesco meetings and receive grants and so forth. In giving help to the new Federation Unesco had not acted entirely unselfishly because it knew that it could not get on in the many fields of its work unless it received help from such non governmental organizations.

Dr BROCK CHISHOLM director-general of the World Health Organization, said also that the first World Health Assembly had instructed its Executive Board to take such action as it might be able to take within its financial capacity on the recommendations which might issue from the World Federation or from the Congress.

### Enlarged Concept of Mental Health

The Congress listened finally to two important statements summarizing the work of the Congress itself and of the International Preparatory Commission and the commissions in the various countries which had preceded it. Eighteen of these national commissions or discussion groups had presented written reports, and these were ably condensed by Mr LAWRENCE FRANK director of the Caroline Zachry Institute of Human Development, New York. Professor J C FLUGEL chairman of the Programme Committee of the Congress, in a further summary, said that the ambitious programme of the Congress had meant an enlargement of the usual conception of mental health.

"It has involved a new attitude on the part of the medical profession. Here I may allow myself a few words as a non-medical academic psychologist. I think it was H G Wells who said many years ago that psychologists had nothing to do with the mental ills of mankind. Who with a sick soul would go to the psychologists? It is the medical psychologists who have changed all that, and the methods with which we approach the problems of mental health in their new and wider significance are largely methods which have come from the field of medical psychology. But it is remarkable—a fact to which some non-medical psychologists have drawn attention—how completely our medical colleagues have overcome their natural scruples about the enlargement of their domain and the handing over of a portion of their province to others who were not thought previously to be concerned with these spheres. Health was regarded as the sphere of the doctor, not often of the teacher, certainly not of the psychologist, who was expected to restrict his work to the laboratory.

But it has been largely through the work of the doctors that psychology has come into more intimate contact with ordinary human life. I wish to testify to the extraordinary generosity and grace with which the doctors among us have handed over a portion of their province and allocated some of their labours to another sphere. Transitions of this kind do not always occur with sympathy. I remember in my youth the objections of the philosophers to admitting that psychologists had any particular place that was not the intimate concern also of the philosopher. The philosophers in my day felt that they were competent to deal with all the problems of psychology. But medical psychologists have not taken that attitude. In the course of our discussions we have heard how mental health considerations must be borne in mind by a whole host of people to whom these notions previously were quite foreign."

Dr REES in closing the Congress, commented regretfully upon the absence of a Russian delegation. Such a delegation had been fully expected even until after the Congress had begun.

A programme was sent to the president of the Academy of Medicine in Moscow, and he would receive a copy of the proceedings in due course. With regard to the World Federation for Mental Health, one of the first acts of its Executive Board had been to request the twenty or more members of the International Preparatory Commission to become an advisory intra-professional committee for the Federation.

The President concluded his remarks with warm expressions of thanks to all those in various parts of the world who had helped to make this event so memorable and successful. Dr Rees himself received a great tribute of acclamation from the whole body of the delegates.

## Preparations and Appliances

### AN AID FOR DEFECTIVE DISTANCE AND NEAR VISION

Mr F W G SMITH ophthalmic surgeon, Kent and Canterbury and Margate Hospitals, writes. This device, which should be used with the patient's correct distance glasses, unless emmetropic, was evolved to provide a simple aid for those persons usually elderly, who were unable to have the vision of their better eye improved beyond 6/60 or 6/36 owing to corneal, lens, or, particularly, retinal changes. I have not had much success with telescopic spectacles, their equivalent in contact lenses or other methods in old people, as senility and lack of concentration were contraindications in many cases, these conditions may apply to a lesser extent to the aid which is here described.

This instrument, which has the trade name of "dualocular," is used like a telescope and can be carried slung round the neck on a ribbon. It is made of light plastic material. Magnification is about  $\times 2\frac{1}{2}$ , and 6/60 vision may be improved to 6/24 or 6/18. For reading, the movable lens is swung out, print is

focused at about 9 in (22.5 cm). J1 is enlarged to J4. To obtain fuller magnification the eyepiece end can be held very near the print and the movable lens swung out. The eye should be about 12 in (30 cm) away to bring the object into focus. Additional illumination is required for this method.

The "dualocular" is made for me by Messrs R S J Barton and Partners, 27, Friars Close, Whitstable, Kent, and the present price is £2 10s. Instructions are supplied, which include a warning that the aid should be used only by those who have had their eyes examined and that it should not be considered a cure for failing vision.

The Birmingham Executive Council has approved in principle a scheme for the establishment of a central telephone control for doctors. It is suggested that there should be an emergency call-sign and that anyone needing a doctor in a hurry would ring this number. If for any reason they were unable to get through to their own doctor, the operator in the control room would then find the nearest available doctor who could take the call. The views of the local medical committee and of the Ministry of Health on the proposal are to be obtained. The council accepted in principle recommendations for the association of groups of doctors with the maternity and child welfare services provided at clinics near their practices, and also for the association of district nurses, midwives, and health visitors with the groups of doctors. The council also recommended that general practitioners should have direct access to hospital pathological and x-ray departments, and this matter will be taken up with the regional hospital board and the board of governors of the teaching hospitals.

## Correspondence

### Organization of Consultants and Specialists

SIR—The information on the new move on the above subject contained in your leading article (Aug 14, p 343) and in the report of the first meeting of the new Central Consultants and Specialists Committee (*Supplement* p 81) will come as a surprise and shock to many specialists who have been thinking that as far as the B M A was concerned the manner of their representation had been settled at the Annual Representative Meeting last June. As this move to explore the prospect of collaboration with the Royal Colleges and Scottish Corporations, even to the extent of setting up a joint committee, to which, to some degree at least, the new Central C and S Committee would be subsidiary, has now been made public in the *Journal* and in the *Lancet* of Aug 7, it should be considered by the local and regional committees of specialists and it is necessary to make some comment on the subject.

Specialists will be surprised that any move at all has been made to discuss with the Colleges the formation of a joint committee. For the constitution of the new Consultants and Specialists Committee states that it will "consider and act upon all matters affecting those engaged in consulting and specialist practice," and will be autonomous. Further, it had been made clear that at least in the eyes of the Association it would be the only negotiating body for consultants and specialists. No one therefore would expect that the new committee would be made in any way subservient to any other body.

It must be stated that this move was not initiated by the new Central C and S Committee. When the committee was informed of the conference of the President and Chairman of Council of the Association with the Colleges it decided that further conference should only be exploratory of the possibilities of collaboration in the interests of specialists and further that reference must be made to the regional committees before any decision was taken.

Everyone wants to see ended if possible the present unhappy position of specialists, divided in their loyalties and representation and consequently weak in negotiation upon the terms and conditions of their employment in the National Health Service and upon other matters. It was for that reason that we have striven to set up a completely representative organization for all specialists based on the functional units of hospital staffs, with elected regional committees from which the majority of the central committee would be elected. We agreed to set up this organization through the B M A, first because that was clearly the only body with the resources available to allow us to be immediately and strongly represented, time being at present an important factor, and, secondly, because the specialists could in that way be represented through the same body as all other branches of the profession and the unity of the profession thus be preserved.

It is evident that most specialists have approved of this organization in preference to the proposal of Lord Moran for an *ad hoc* committee of the Colleges and the various special-practice associations. For they have seen in the latter merely a recrudescence of the old Consultant Services Committee, which was ineffective, and have understood that an *ad hoc* committee for the continuous representation of professional interests could not be as efficient or acceptable as one built up democratically from the periphery to the centre. They have also known that the special-practice associations, as for example the British Orthopaedic Association to which I belong, are not constituted for medico-political purposes but are purely scientific bodies. So also the Colleges are clearly academic and examining bodies undemocratic in their constitutions and in their Councils representative very largely only of the teaching members among specialists. There can be no doubt that despite their loyalty to the Colleges as academic institutions most specialists not only do not want the Presidents and Councils to intervene in medico-political affairs or to represent them in negotiation on terms and conditions of employment, but actually resent their attempts to do so because they have no means of keeping in touch with the rank and file. However desirable it may be, therefore, that

harmony shall exist between the B M A organization and those who control the Colleges it is unlikely that specialists will accept a position in which, through the existence of a joint committee, the authority of the Central Consultants and Specialists Committee to consider and act upon all matters concerning special practice might be impaired. On the other hand it appears obvious that the true functions of the Colleges are examining, research, and postgraduate education, as Lord Webb-Johnson has himself indicated (July 3, p 46). If a joint committee is set up it will be difficult to define its functions and powers and for it to operate without offending one or other of its constituents.

There is a danger that in trying to please everyone in this matter we shall please no one. Certainly if the authority of the Central Consultants and Specialists Committee is impaired, the specialists attached to the non-teaching hospitals will have to reconsider whether they should continue to be represented through it or should revert to and build up their own association as a Regional Hospital Staffs Association. For it is clear that while they have consented for the sake of harmony to equal representation on the Central Consultants and Specialists Committee with the representatives of the teaching hospitals (which of course they greatly exceed in numbers of their hospitals and personnel), they would be likely in a joint committee with the Colleges, the Councils of which are mainly composed of teachers, to find themselves in a minority of perhaps one in five or more. Unfortunately there have been and continue to be (*vide* the medical membership of the Central Health Services Council) many indications to the non-teaching specialists that they are to be assigned a minor place in status and in the councils of the Health Service. For that reason they formed their own association several years ago and they may return to that if they cannot feel sure of the protection of their interests in the B M A organization. If that should happen, that organization would fail by losing the greater part of its support.

As one who has taken some part in forming the new organization I hope that nothing will be done now to destroy it by weakening its authority. As a Fellow of one of the Colleges for many years I also want to see the Colleges remain true to their proper functions and in that way best maintain their dignity and influence—I am, etc.,

Bournemouth

N ROSS SMITH

### Post-pituitary Extract in Obstetrics

SIR—The method whereby posterior pituitary extract is given by a slow-drip intravenous infusion of a dilute solution, as advocated by Mr G W Theobald and his colleagues (July 17, p 123), is attractive so far as the treatment of uterine inertia is concerned. In the belief that it probably more closely resembles the physiological output of oxytocin by the pituitary, I have used a similar technique in a few cases during the last twelve months, and within the limits of a small experience I can confirm some of Mr Theobald's statements. Our procedure consisted in giving a stronger solution (one part of "pitocin" in 1,000 parts of 5% glucose saline), but at a slower rate (maximum 16 drops per minute and often less). The total dose only once exceeded 10 units of pitocin. The women treated were all suffering from long-standing uterine inefficiency which had failed to respond to the usual remedies, and all had been in labour for not less than 48 hours. The strength and frequency of uterine contractions were increased in proportion to the rate of the drip and could be controlled almost at will. The rapid response of the uterus to either speeding or slowing the rate of infusion appears to offer a degree of safety to mother and child which is lacking when single doses of oxytocin are given intramuscularly or subcutaneously.

In some cases of inertia the beneficial effect of the oxytocin drip is remarkable, but unfortunately the results are not always good. This is almost certainly because inertia varies in type and aetiology. The effect of the treatment is to enhance the activity of the uterus, but it does not apparently change the quality of the action. Thus, when the inertia is of the hypertonic type, or when a quiescent upper segment is associated with high tone and increased resistance in the lower segment and cervix, the efficiency of the uterus is not improved. The uterine contractions are increased but remain incoordinate, as evidenced by the patient's symptoms and by the failure of the cervix to dilate. Our observations to this effect appear to be

borne out by the account of Case 7 in Mr Theobald's article. Moreover, I am informed by Dr S R M Reynolds, who also has been using oxytocin by intravenous drip and recording the effects on three areas of the uterus simultaneously by means of the strain gauge multi-channel tokodynamometer," that his results indicate that posterior pituitary serves only to augment existing uterine motility and in certain cases results in increased activity of the middle zone of the uterus rather than improved expulsive contractions of the fundus, thus hindering instead of assisting the progress of labour.

Mr Theobald points out that an intravenous oxytocin drip does not take pride of place over analgesics and anti spasmotics in the treatment of inertia, and it seems wise to add that even when these have failed it should not be given without first taking care to exclude as far as possible incoördinate uterine action. In this condition it is of no value and it may make matters worse, even to the extent of producing a contraction ring. Its real indication is the uterus which is hypotonic but whose polarity is not disturbed. Even then we have found that after prolonged treatment the uterus which initially responds well may become refractory and cease to react when the rate of the drip is increased. This is in keeping with a similar phenomenon which can be seen when intramuscular injections of posterior pituitary extract are repeated at frequent intervals—I am, etc.

T N A JEFFCOATE

### Treatment of Typhoid Carriers

SIR—The careful inquiry into the efficacy of penicillin and sulphathiazole on chronic typhoid carriers reported by Drs R M Fry, R E Jones, B Moore, M T Parker, and S Thomson (Aug 7, p 295) is particularly commendable for the strict criteria demanded before a cure was assumed. It is to be hoped that other forms of treatment will be examined with equal care before being offered to patients. In particular this should apply to surgical treatment, for it is possible that surgery may be more frequently advised now that the ineffectiveness of current chemotherapeutic methods has been demonstrated.

Attempts to cure the chronic typhoid carrier by removal of the gall-bladder presuppose that this organ contains the only focus of infection in the body. For this belief there is no pathological evidence. Animal experiments have revealed lesions in the wall of the gall-bladder, but these have not been observed in human cases. The bacilli certainly flourish within the bile in the gall-bladder and evidence of a mild cholecystitis is generally found, but no focus of bacilli has been found in the wall, indeed there is still much in favour of Gerbat's belief that the gall bladder merely acts as a human test-tube containing the bile culture medium in which the organisms flourish so readily. Furthermore, even if it could be established that there was a permanent focus in the gall-bladder, there is no way of establishing that there are not other foci, either primary or secondary, which would of course be uninfluenced by cholecystectomy. Thus Saphir *et al*<sup>1</sup> found that, although they could sterilize the bile (eight negative duodenal intubation specimens being their evidence for this), none the less faecal excretion of bacilli continued in sixteen out of twenty-one cases, this strongly suggested the presence of other foci either in the intestines, the bile ducts, or elsewhere. Indeed in Fry's series the reappearance of bacilli after apparent sterilization also raises this suspicion.

Despite these difficulties many authorities regard cholecystectomy as a certain cure. Many claims of successes have been made but subsequent investigation has shown that many were based on bacteriological criteria of cure which are now held to be invalid. Thus the cure rate of 75% quoted in the report of the Infectious Diseases Subcommittee of the Research and Clinical Committee of the Royal Medico-Psychological Association is based on unstated criteria of cure and upon work done at several different laboratories and hospitals. Again Browning *et al*<sup>2</sup> were forced to reject most of the reported cures as being invalid although three of their own cures were strictly tested. Furthermore there is a long unpublished list of failures reaching widely round the globe which, though they are unlikely to find their way into the medical press, would substantially dilute the percentage of claims made on the published series of very few cases. It is doubtful if much hope of permanent cure can

be offered to the chronic carrier by cholecystectomy, and it is hoped that in future it will only be advised after careful thought—e.g., in young patients with a short history (and therefore with more chance of the gall-bladder being the only focus) whose bile is persistently positive and who are incapable or unwilling to control their potential danger by other means.

Lastly, it is more than probable that before long an efficacious chemotherapeutic remedy will be discovered. In the meantime attention should be directed to the bedside, for it is often through careless initial surveillance that carriers escape. Anyone who has dealt with over two hundred cases of typhoid must be frightened by the realization that on the law of averages he should have discovered from four to ten carriers. But more important still is the possibility that chemotherapeutic remedies may be effective in the early stages of the carrier state, proof that these remedies have no beneficial effect in a series of carriers of between three and sixteen years' duration does not imply that they will have no effect if given in the early stages. Vigilant testing of stools should therefore continue with added zeal, and when a carrier is detected intensive treatment should be commenced at once with penicillin and sulphathiazole or with iodophenolphthalein.<sup>3</sup> Despite the inevitability of thus including in the treatment those convalescent carriers who might recover spontaneously, such a procedure might none the less preclude some chronic carriers from developing—I am, etc.,

### The BBC and the NHS

SIR—It is a pity that a serious paper should publish a letter containing so many inaccuracies as that on "The BBC and the National Health Service" by Dr Ff Roberts (July 24, p 224). Since those of your readers who did not hear the broadcast may have received a very false impression I should appreciate the opportunity of making a few corrections.

1 Your correspondent writes, "We heard a mother's dread of the voluntary hospitals transformed into joyous confidence in the same hospitals nationalized. No such incident occurs in the programme (I write with the script before me). A mother certainly showed a certain amount of anxiety when the doctor told her her child should go into hospital. This is a natural reaction, since the layman connects a stay in hospital with serious illness. No comparison, however, was made between voluntary hospitals and nationalized hospitals until the question of expense came up, when it was pointed out that, whereas a charge used to be made according to the patient's financial status, now no payment is necessary."

2 Your correspondent writes, "The hero of the piece was a surgeon to him came a Mr Venables, intended to be a typical *nouveau riche*. He wanted to know whether he should remain a private patient or become a public patient." Mr Venables naturally went to his own general practitioner to discuss this question—not to a surgeon. This point, of course, is scarcely worth mentioning except that it illustrates the generally low standard of accuracy throughout the letter. Venables was portrayed as a reasonably sympathetic character—a man of shrewdness and common sense. He was not "intended to be a typical *nouveau riche*" (your correspondent, by the way, professes a curious omniscience with regard to my intentions, which he mentions several times). The conversation between Venables and his doctor was intended to be of interest to those people who are able to afford to remain private patients and therefore are faced with the problem of deciding whether it is worth the expense or not. It was pointed out that the private patient had certainly enjoyed considerable advantages over the panel patient in the past and that it appeared likely that he would continue to enjoy advantages over the national patient in the future, but perhaps not quite so many. Venables decides to remain a private patient. Your correspondent says that he shows his astuteness but comments that this was contrary to my intentions. Why should he think so? We are all free to choose our luxuries in accordance with our incomes and personal tastes. There is no question of either praise or blame.

3 Your correspondent writes, "Playing opposite to the hero was the villain, personified of course by the medical superintendent." I was somewhat mystified by this statement, since no medical superintendent appears as a character in the programme at all. A medical superintendent is, however, mentioned in one anecdote concerning a case of torticollis—an anecdote which happens to be true. Your correspondent writes, "The superintendent was for discharging her (the patient), but the hero nobly stood his ground, thereby risking

his career in the interests of humanity" Unfortunately, your correspondent has completely missed the point of the story, which he appears to think was told against the "bad old days" The opposite is the case The story is told by a physician who fears that the new Service will threaten the independence of medical opinion and action He tells of this clash with the medical superintendent of his hospital, pointing out that his refusal to comply with the medical superintendent's advice did not involve any risk for him, since he was in no way dependent on the medical superintendent for his livelihood He expresses a fear that similar independence might be costly in future

It is to be regretted that your correspondent did not take the precaution of checking his facts before making this venture into radio criticism—I am etc,

Broadcasting House  
London W1

NESTA PAIN

### Excretion of Antimony

SIR—With reference to your annotation (July 10, p 83) on this subject, pharmacologists elsewhere have confirmed the records<sup>1</sup> made in Egypt in 1931 and subsequently showing that half the amount of antimony injected may be recovered from the excreta within a month This would account for the re-appearance of ova in the excreta of patients undergoing the treatment with massive doses here in Natal with the sodium equivalent of tartar emetic as recommended in Southern Rhodesia It is unreasonable to rely on the mere absence of ova from the excreta as evidence of the destruction of the adult worms until they have had time to recover from the effects of the drug or have been demonstrated by post mortem examination

I was asked to examine a tobacco planter whose skin test had given a positive reaction for schistosomiasis in Southern Rhodesia As he showed no signs or symptoms of infection and his eosinophils were only 2.5% I did not consider that any treatment was indicated He stated that his natives refused to submit to the treatment adopted for a rapid cure since several of their colleagues had died from its effects—I am, etc,

### Diabetic Coma

SIR—I have read with great interest Professor R H Micks's article on diabetic coma (July 24, p 200) and Drs R D Lawrence and Wilfrid Oakley's letter on the same subject (Aug 7, p 310), and I should like to add one or two points to the discussion Treatment of diabetic coma must be directed towards remedying not only the metabolic derangements but also the concomitant biochemical changes and associated disturbances which occasionally culminate in sudden death

Dr Lawrence and Dr Oakley rightly stress the need for careful administration of insulin in the average case of pre coma, whereas the case of profound coma requires heroic treatment with very large and repeated doses of the quickly acting soluble insulin It must always be remembered that circulatory collapse is the most dangerous feature of diabetic coma, and the patient must be treated for shock—the maintenance of blood pressure being as important as in any other condition of shock Fluid and food by mouth should always be withheld, since they are dangerous at this stage The patient must be kept warm to prevent further heat loss, and aspiration of the gastric contents to prevent dilatation of the stomach with subsequent possible inhalation asphyxia—a definite cause of death in diabetic coma—should never be omitted Professor R H Micks draws attention to the importance of gastric aspiration in the management of diabetic coma

An intravenous saline drip, where necessary, to replace fluid loss, thereby correcting dehydration and the blood chemistry, is a very necessary part of the treatment of all cases of diabetic coma Professor Micks states that Root's statistics strongly support his claim that normal saline is the only intravenous injection needed in diabetic coma and that other authors have asserted that alkalizing solutions are necessary or that plasma should be used Of the American authors Root and Joslin do not advocate alkalizing solutions, while Russell M Wilder, of the Mayo Clinic, recommends the administration of alkali if the carbon dioxide combining power of the plasma is less than 20 volumes per 100 ml I believe that the decision to give or withhold alkalis depends on simple basic principles

The indication for the administration of alkali is marked hyperpnoea and if this symptom is present the administration

of alkali can be a life-saving measure In the average case of diabetic coma or pre-coma there is not the distressing hyperpnoea which is a feature of some cases of profound coma Where there is marked hyperpnoea, however, administration of alkali—25 g of sodium bicarbonate in 5% solution intravenously—should always be administered, as death from respiratory paralysis occurs in uncorrected severe diabetic acidosis through over-stimulation of the respiratory centre It is true that insulin in the presence of adequate glycogen will correct the acidosis and therefore the hyperpnoea, but this is a comparatively slow process Intravenous alkali, on the other hand although not preventing acidosis will rapidly remove the dangerous symptom of hyperpnoea The importance of aspiration asphyxia and respiratory failure due to marked hyperpnoea as causes of sudden death in diabetic coma have not received the prominence they merit and cannot be over-stressed

Although there is a difference of opinion as to whether glucose should be given during the treatment of diabetic coma, it is certainly wise to give glucose in those cases receiving large amounts of insulin, particularly after the first 6–12 hours, 1–2 g of glucose for each unit of insulin injected will guard against hypoglycaemia, which is a constant danger when repeated large doses of insulin are administered Therefore, if it is not practicable to perform frequent estimations of the blood sugar level glucose should always be given in order to guard against hypoglycaemia, except in the earliest stages of treatment when the blood-sugar level is always high—I am, etc

Maldstone Kent

GEORGE R W N LUNTZ

### Peritoneoscopy

SIR—I read with great interest the paper by Mr John Hosford on peritoneoscopy (Aug 14, p 348), but before the term becomes part and parcel of our medical vocabulary I should like to follow Rendle Short's example and offer "coelioscopy" as an alternative "Peritoneoscopy," in addition to being clumsy and cacophonous, would mean an instrument for viewing the peritoneal membrane and not necessarily the abdominal viscera The other term suggested in the article, "laparoscopy," being derived from λα-άρα the flank, is also a misnomer, as is "laparotomy", the only true laparotomy is a kidney incision

On the other hand, "coelioscopy" (or perhaps more correctly "coeliascopy")—a far neater word than the others—means the examination of the abdominal contents (κοιλία), which is the true purpose of the operation In general, I feel that more care should be taken with our vocabulary Had this occurred in the past we should have been spared many glaring errors I suppose it would be pedantic to quarrel with "appendicec tomy," but surely "hypophrenic" or "subdiaphragmatic" are preferable to the hybrid "subphrenic," and "proctoceles" to "rectoceles"?—I am, etc,

Guildford

A BARNESLEY

### Choosing a Career

SIR—It seems to me that in recent months we have devoted a great deal of attention to monetary considerations resulting from the passage of the Health Service Act The Spens Report has still further accentuated the financial aspects of medical work and appears to have justified the demand for raising the standards of direct payment in all clinical posts From the university point of view this has been followed by increases in the salaries of professors and lecturers in all faculties—medical and non-medical alike The young graduate on the road to specialism has perhaps come best out of the deal and if the younger generation of teachers in the preliminary subjects has been overlooked it broaches a question which demands an immediate answer

In my view, however, elements other than those of remuneration should have the attention of the potential doctor after he has, from about the time of his third year onwards surveyed the field of medical service His object should be that of selecting from this field the type of work which would allow him on retiring to look back with satisfaction on his life's journey They are, indeed, fortunate who can do this In our profession at the present time there is a wide range of choice open to candidates Given a certain standard of ability coupled with

Basingstoke, Hants

industry, energy and dexterity, and perhaps ambition, the student must be entitled to decide for himself in what direction his work might be expected to bring its own reward. In coming to a decision personal trends must be given due weight.

1 There are those whose chief thrill comes from research, in following out a line of thought by experiment and logical reasoning, hoping in the end to reach a worthwhile result. For them medicine provides an ever-widening horizon, each fresh discovery a stepping-stone to the next.

2 Others are thrilled by imparting instruction on established facts and possible theories to individuals or groups. We speak of the "born teachers," whose gifts both bring and bestow enjoyment.

3 Others still are attracted by the thrill of being the bearers of hope and confidence to the sick as they are found in the wards and out-patient departments of our hospitals. Valuable equipment for these is what, for want of a better term, we call clinical instinct, and for them there is again a wide choice among the many departments of clinical work, each with its own peculiar attraction.

It is my experience that all these qualities and ideals are seldom combined in a single individual, and at a time when money prizes are unlikely in the future to compare with those of the past, but where for every medical graduate a livelihood is assured, a young man or woman should be encouraged to follow that course in which the work itself would be a continuous joy, and from which he or she might be expected in the end to obtain the maximum of individual satisfaction. If I might be permitted to end on a personal note it would be one of thanks to an old teacher, the late Professor James Lindsay, who at a critical moment gave me advice which I pass on to those faced to-day with the entrancing and decisive problems of youth.—I am, etc.,

Belfast

S T IRWIN

### Prevention of Venereal Disease

SIR—The numerous correspondents in the *Journal* of July 31 (p 268 *et seq*) appear to have missed the essential points of Lord Horder's letter (July 17, p 171), and the simplest way to reply to the various issues raised in their letters is to restate the main heads of the campaign. The campaign of the NSPVD is directed towards the enlightenment of the public on the following matters:

1 Over a long period of years the abundantly proved fact that VD is easily preventable has been prevented from reaching the public, and in spite of lavish public expenditure on other methods VD has increased.

2 The Report of the Government-appointed Trevethin Committee settled once for all the scientific fact that VD is easily preventable. Abundant scientific evidence was laid before that committee, and this was confirmed by overwhelming evidence from myself and others as the result of wide experience in reducing VD in the Services. Dramatic reduction in VD has always followed the introduction of reasonably effective self-disinfection.

On the subject of practicability for the average person the Report says: "We see no reason to doubt that an intelligent man, if furnished with reasonable instructions, could in favourable conditions effectively disinfect himself." A study of the actual instructions will convince anyone that no high degree of intelligence is required. The process is so simple that "official skilled supervision" of the disinfection is obviously superfluous. Practical experience, moreover, has shown conclusively that civilians will not seek such assistance, and that in the case of the Services the introduction of supervision and the unnecessary elaboration of the procedure have been the chief causes of the apparent lack of success on account of evasion. Officially supervised disinfection never has been, and never will be, successful on account of the psychological factors involved.

3 The Trevethin Committee Report replies effectively to the allegation that knowledge about preventives would lead to increased promiscuity. On this subject the Report says: "It is urged by some that any system of disinfection would tend to increase the number of exposures and to raise the disease rate. We have received no evidence of facts in support of this view and we are inclined to think that those who hold it attach too much weight to the deterrent effect of the fear of the disease."

Conclusive evidence was supplied by myself and others that a campaign of prevention of self-disinfection in any area was often followed by a decrease in promiscuity because the instructions given furnished the plainest proof of the danger of infection.

4 Not only is the spread of this important knowledge prevented but if it does leak out the law prevents any practical application. Incredible as it may seem, it is actually illegal for a chemist to sell to any customer the necessary materials for prevention accompanied by instructions for use. This continues in spite of the fact that the Trevethin Report in 1923 recommended that the law should be altered. Not content with compulsory ignorance the obstructionists prevent any useful application of any leakage of information. Could fanaticism go further?—I am, etc.,

R A LYSTER

Chairman, National Society for the  
Prevention of Venereal Disease

London W 1

SIR,—Statistics can be used to prove most things, and there are statistics to prove that prophylaxis is useless in the prevention of venereal disease. One instance will serve. In a certain distinguished battalion in Delhi 18 men contracted hard chancres in one month. Inquiry proved that all these men had used the unit prophylactic ablation centre, and had stated so in the prescribed form which men who contracted VD had to complete. This would seem to prove that prophylaxis was useless. Investigation of the forms, however, showed that the men had all exposed themselves to infection at 10 p.m. on various evenings during the month, had each used the P.A. room 15–20 minutes later, and that each had reported at the medical inspection room at 8 a.m. on the morning following exposure with a hard chancre.

I took a close interest in the prevention of venereal disease during the eighteen and half years I spent in India, most of it as a hygiene officer, and I wish to say that I have seldom found a British soldier in hospital with VD who had not used the P.A.C., but also that I have never, after inquiry, found a soldier in hospital with VD who had used the prophylactic ablation centre at the proper time. The centre had been used after the disease showed itself. On my visits I always used to ask the P.A. room orderlies the same question, "How many men have you known getting VD who had used the P.A. room at the proper time?"—i.e., within an hour or so after exposure—and the answer was invariably the same, "None sir." Early washing with soap and water would probably prevent 99 cases out of a 100. The use of mercurial cream after washing would make it as near a certainty as makes no difference.

Owing to the circumstances prevailing in a British division in India during the war it was decided not to establish unit P.A. rooms. Instead, the likelihood of infection if they exposed themselves was impressed on all ranks, and also the value of thorough washing on return to their quarters, using their own soap and towel, and then applying mercurial cream. Steps were taken at the same time to see that prophylactic packets were available for all, easily and unobtrusively. The results fully justified these measures.—I am, etc.,

Public Health Branch  
Control Commission for Germany

W STRELLEY MARTIN

### Whooping-cough and Measles

SIR—In the spring of 1938 an epidemic of measles (morbilli) coincided here with an epidemic of whooping-cough. Of 57 consecutive cases of measles seen by me, 55 were children and 2 were adults. Among the 55 children there were 46 cases of measles alone, 7 of measles developing during whooping-cough, and 2 of whooping-cough developing during measles.

Of the seven who had whooping-cough first and measles during its course all took a normal course without complications, and in two cases there was a suggestion that the whooping-cough was improved by the measles. Of the two with measles first and whooping-cough during its course one progressed to bronchopneumonia and the other was normal. Of the 46 cases of measles alone ten developed some complication or ran an abnormal course. Two had asthma at the height of the rash, never having had it before, one developed a persistent nasal catarrh, two developed erythema nodosum in the second and third weeks respectively with fever, one had joint and abdominal pains for four days before the rash came out and was unable to pass water during the third and fourth days of the rash, two had coughs persisting for more than 14 days from the commence-

ment of the rash, one had double otitis media, and one had a purpuric rash

From this small number of cases it would appear that measles developing during the course of whooping-cough does not necessarily add to the severity of either disease, but the same cannot be said of the converse Dr B L Hodge (Aug 7, p 312) drew attention to a similar double epidemic, and his observations would appear to confirm this view—I am, etc,

Redhill Surrey

L J BARFORD

### Fibrositis

SIR—I should like to take up cudgels with Dr James Cyriax over his article on fibrositis (July 31, p 251), as I feel he is showing indecent haste in interring this condition. The essence of his case is that symptoms commonly attributed to primary fibrositis are really caused by derangements of the spine, and to prove this he compares the symptoms with those of such conditions as lumbago and brachial neuritis due to disk lesions. From certain similarities he draws the conclusion that fibrositis represents the lesser degree of these and related conditions. In stressing the similarities he glosses over the differences.

Observations made on oneself may have an element of bias in them but as an occasional sufferer from both lumbago and fibrositis I have had opportunity to study both conditions at leisure. With regard to lumbago I am in entire agreement with Dr Cyriax. The onset, after what one might term postural indiscretions such as an afternoon's gardening, lifting heavy weights off the ground, etc., followed by diffuse aching pain in the lumbar region combined with inability to fully extend the back—the whole lasting several days or weeks—bears the hall mark of a spinal derangement.

Primary fibrositis, on the other hand, has a curious tendency to occur with changes of climate, but bears no relationship to exercise or posture. Subjectively its pain does not feel to be of the same quality as lumbago. It is a disease of tender spots each of an area so small that it can be accurately localized with the finger tip. It is not only confined to the shoulder girdle or the lumbo-sacral region, but, when extensive, tender spots are found over the insertions of the muscles and their bellies throughout the trunk limb, over the scalp and over the backs of the metacarpals and phalanges—in places, indeed, where there is no muscle interposed between skin and bone. The condition is bilaterally symmetrical to an extreme degree and tender spots may be found in the territory of so many spinal nerve segments as to make one shudder for the integrity of one's vertebral column—should Dr Cyriax's theory prove right.

The response to treatment does not suggest a spinal lesion as marked and permanent relief may be obtained from massage and heat applied to the tender spots, and the condition will improve more gradually though nothing is done. The spine need not be touched to effect a cure, and one wonders if time may not be the chief therapeutic agent when spinal manipulation or traction is used.

Finally, as regards aetiology this may be under discussion but my own feeling is that the lesions lie in the fascial sheaths covering both muscular and bony structures, and that the muscle spasm which is such a feature of the condition is merely protective to avoid stretching a tender fascia—I am etc

London N 4

R G BENIAS

SIR—When Dr James Cyriax (July 31, p 251) calls primary fibrositis an imaginary disease he is in good company, but that fibrositis coming on for no apparent reason is always due to an articular lesion, as he states, seems open to doubt. I should like to quote the following case.

On Nov 2, 1946, a district midwife, aged 24 years, recently married, no children called at my house for advice regarding a neck stiffness which had developed two or three hours previously. On examination she had spasm of the upper margin of the left trapezius muscle, which was easily palpable and tender to touch. Obviously this was a true fibrositis, if the disease exists. Having some doubts about this, I made further inquiries. She admitted to having had a few colicky pains during the day, and on examination was found to be tender in the left fornix. A diagnosis of ruptured ectopic pregnancy was received by the patient with such incredulity as reflected

doubts on my sanity. However, the following day she had a laparotomy and was found by Mr. Theobald, who had seen her in consultation with me, to have a ruptured ovarian pregnancy, with free blood in the peritoneum. In this case the last menstrual period had started about 17 days before the illness and any faith in fibrositis on the doctor's part would have caused the diagnosis to be missed. But this was *not* an articular lesion, nor was there an apparent reason for the fibrositis—I am, etc,

Shipley

H S RUSSELL

SIR,—In his article on fibrositis (July 31, p 251) Dr J Cyriax has fallen upon a concept which has been promulgated in osteopathy for the last 70 years. The article, though condemning one aspect of the osteopathic theory, is essentially the theme of osteopaths for all these years—namely, that the spinal lesion is the cause of most local spinal and referred somatic pains.

The main difference now is that Dr Cyriax stresses the intervertebral disk as being the faulty structure, whereas osteopathy stresses the apophyseal joint as being the site where significant changes have occurred. The probable truth is that both are to blame, sometimes one, sometimes the other, and frequently both together. It is however not possible to tell which part of the spinal joint is the offending structure except by inference because, as Kellgren has shown, all deep pain is segmental in its manifestations.

With the advent of disk surgery and visible proof that prolapsed disks cause lumbago, sciatic pain, and brachial pain, the disk is now blamed for everything which happens to a spinal joint. But consider the pathology and the possible effect of manipulation. How can one manipulation, as suggested, normalize a torn cartilage? It might dislodge the offending piece from a sensitive structure, just as it is possible to manipulate a displaced cartilage in the knee and obtain relief straight away, but healing requires weeks. If one manipulation is effective, then the more rational explanation is that old adhesions in the capsule of the apophyseal joints have been snapped. The analogy of adhesions in a stiff knee is complete. One manipulation frequently cures especially if the adhesions are old and brittle.

The osteopathic type of manipulation, while making use of specific forced movements for the purpose of breaking adhesions, does at the same time use gentle articulation of all the joints in the area of the lesion with the object of increasing local circulation and restoring normality there. The osteopath advocates a series of gentle manipulations without anaesthesia and rhythmic traction is an important part of treatment. This probably assists in the healing of the intervertebral disk if and when it is damaged and explains much of the success of their method—I am etc,

London W 1

ALAN STODDARD

SIR—Dr James Cyriax's statement (July 31, p 251) that primary fibrositis is *imaginary* is rather startling. Does he think the following cases are due to intervertebral lesions and not primary fibrositis?

A male 72, has physical lesions due to fibrositis in both feet, calves thighs at brim of pelvis, around the spines of the vertebrae, in the thoracic walls, and also panniculitis (fibrosis of fat) at lower regions of thorax and around and between the breasts, also physical lesions in the neck and temporal regions, no sepsis found, also no rheumatoid arthritis nor osteoarthritis present. His posture and carriage are excellent. Fibrositis commenced at the age of 16.

A woman, 56 had pain in lower back for 20 years, and recently pain in the left lower abdomen. She had seen two physical medicine specialists, an orthopaedic surgeon, a consulting physician and received every imaginable treatment. She was found to have fibrosis of fat around the pelvis and hips and a mass of fibrosed fat in left lower abdomen. She received 19 treatments of deep massage and has remained free from pain for 2½ years. No sepsis, osteoarthritis or rheumatoid arthritis, nor the usual physical signs of fibrositis found.

Good fitting dentures suddenly become painful and are eased, and when this process has been repeated several times the dentures are ruined. In many cases it is due to fibrositis of the upper and lower jaws and can simply be remedied by deep massage a few times.

Does Dr Cyriax manipulate as a rule with or without a general anaesthetic? Surely it is very difficult to believe that any of these cases can be *due entirely* to intervertebral lesions. It should be mentioned that in the first case the fibrosed mass, already palpable, becomes bigger and more obvious when

there is pain in the anterior aspect of the thorax, and strangely enough a nitroglycerin tablet relieves the pain in, say, 30 seconds—I am, etc,

London W 5

R HALSTEAD DIXON

### Use of Ring Pessaries

SIR—It is always a pleasure to read a broadside from Mr Mortimer Reddington (July 24, p 227), for although some of the shots may be wide, many undoubtedly score. It is certainly true that in the past far too many women have had ring pessaries fitted. When I was chief assistant of the department at St Bartholomew's Hospital it was the custom for these patients to come up one afternoon a week to have their rings changed by students who were undergoing their gynaecological training. They came in great numbers, but I suppose it was because in those days beds were few and the operation was not as safe as it is nowadays.

The ring pessary has, however, in my opinion certain definite uses. It can quite reasonably be advocated in the case of the young woman with descent of the vaginal walls immediately following childbirth where physiotherapeutic measures fail, but it is not fitted to support the tissues till involution has occurred. It is fitted to support the tissues until the baby is weaned and the mother can be operated upon. I think it is also of value to patients who have symptoms but no signs of prolapse. It should be used in those rare cases unfit for operation, and in those rarer cases where the patient refuses operation.

Now a word about the Hodge pessary condemned to be "put away altogether, and for ever." No splint will correct a deformed limb. The deformity must be corrected and the splint applied. If the retroversion is first corrected, then the Hodge will keep it so, provided it is long enough to reach from the posterior fornix to the vulva. I personally regard the Hodge pessary as invaluable in elucidating the cause of backache. I would never contemplate shortening the round ligaments for backache unless either the uterus could not be replaced or the patient's backache not dispersed by her wearing a ring for a short time—I am, etc.

Blackheath

KEITH VARTAN

### Foetus Papyraceus

SIR—The case of twin pregnancy with acute hydramnios treated by abdominal paracentesis (July 24, p 205) is most interesting and Dr R. W. Danziger is to be congratulated on the successful result. It is a pity, however, that more details were not furnished about the "blighted" twin which is simply described as a foetus papyraceus. The interest lies in the aetiology of this condition, which usually follows mechanical compression of the foetus after loss of its liquor amni, the compression may be effected by the fellow twin itself, or more usually by its bag of waters, but in order to produce a foetus papyraceus the compressing force must be adequate to cause collapse of all body cavities, so that maceration may be arrested. Thus the development of a rigid thoracic cage and firm cranial vault would prevent this pathological sequence. An analogy may be drawn between this phenomenon and the preservation of botanical specimens by pressure between sheets of blotting paper, the process of vegetable tissue autolysis cannot be prevented when the structures concerned are too bulky to be dehydrated by compression.

It is generally considered that the development of acute and subacute hydramnios in association with uniovular twinning is due to uneven foetal demands from the common placenta, the interplacental vascular anastomoses ("third circulation") allow the more powerful circulation to withdraw an excess of fluid into one foetus resulting in some way in hydramnios for the larger and dehydration of the smaller twin. In most cases some sort of fluid balance is achieved, but rarely the smaller foetus may perish from fluid depletion, producing a dried, wrinkled specimen which does not undergo maceration and is not very much compressed. This is the mummified foetus, and many authorities fail to distinguish between it and the papyraceus.

In favour of a diagnosis of mummification in the case described is the fact that radiography some weeks after foetal death showed only failure of growth, with no unequivocal signs of compression. In addition the foetal size was considerably smaller than the period of gestation should produce suggesting

impairment of growth before foetal death. Additional evidence would be furnished by the presence of fluid in the affected amniotic sac, which is naturally absent with a foetus papyraceus, and complete infarction of that portion of the placenta supplying the morbid twin—I am, etc,

Birmingham

W G MILLS

### Production of Rh Agglutinins

SIR—In the article by Drs George Discombe and H. O. Hughes (Aug 14, p 329) on the importance of transfusion as a cause of haemolytic disease, the paper by myself and others (*British Medical Journal* 1945, 1, 584) is quoted as having expressed the view that patients afflicted with certain diseases might be especially apt to produce antibodies to antigens which they themselves lacked. No such point of view was expressed in our article. The article concerned itself simply with a report of facts—namely, the truly colossal Rh agglutinin titre produced in response to multiple transfusions of Rh-positive blood, the comparative absence of symptoms in the incompatible transfusions, the technical pitfalls in the typing and compatibility tests, the ultimate outcome of the case, and a brief factual report on the necropsy findings. No opinion was expressed as to the relationship of the ready production of the Rh agglutinins to the patient's disease, nor was it even considered. I have personally never held or expressed the view that patients suffering from certain ailments might be especially apt to produce antibodies to antigens, especially the blood group antigens which they themselves lacked—I am, etc,

Cardiff

R J DRUMMOND

### Independent Doctors

SIR—Your annotation on "Independent Doctors" (Aug 14, p 347) concludes pathetically by saying, "There would appear to be no reason why such a committee [separate organization for independent doctors] should not be set up in the B.M.A." The B.M.A. has, apparently, as short a memory as Mr Bevan. No doctor could avoid being shocked by the knavish way in which the B.M.A. deserted the sound stand it had taken (as a result of the strongly expressed views of the medical profession) when the appointed day drew near.

What is required by all doctors and especially independent doctors, is an active body rather than a talking body such as the B.M.A. If Lord Horder can supply this dire need good luck to him—I am, etc,

Bretby Hall Burton on Trent

R LUNT

### Surgical Anatomy of the Parotid Gland

SIR—I was very surprised to see Mr Hamilton Bailey's article on this subject (July 31, p 245) and to find that he persists in writing in the same vein as in a similar article in the *Journal* of March 29, 1947 (p 404).

When I read the latter-mentioned article I carried out a series of dissections on the parotid region after injecting indian ink along the main parotid duct into the gland. To identify the small ducts within the gland I had to use the dissecting microscope. My findings with regard to the relation of gland to the facial nerve were entirely at variance with those of Mr Hamilton Bailey. I could not display a bilobed arrangement of the parotid with the facial nerve running between two lobes. To illustrate the relationship briefly, let me compare the facial nerve plexus to a trellis-work fence, with the parotid gland, like a creeper, growing from the direction of the buccal cavity and winding itself indiscriminately around the nerve and its branches. I communicated my findings to Mr Hamilton Bailey, previous to my reading a paper on the subject to a meeting of the Anatomical Society of Great Britain and Ireland in London in November, 1947.

I should like to comment on two other points in Mr Hamilton Bailey's article. First the size of the main parotid duct—surely it is larger than a fine hypodermic needle? During my investigation a year ago I could easily insert a hypodermic needle of a substantial calibre into the duct. Because I have not the specimens to hand I cannot say more than that the duct is definitely larger in diameter than that of a fine hypodermic needle and that observation is in formalin-hardened subjects where the tissues normally tend to shrink under the influence of

the preservative Secondly, with regard to the presence of the accessory parotid gland, I should like to know in how many cases he looked for this part of the gland The article leads us to believe that it is an infrequent occurrence I have no figures to quote, but it is my opinion that careful examination would reveal it in at least a reasonably large percentage of cases—I am, etc,

Aberdeen

JOHN MCKENZIE

### Medical Photography

SIR—With thirty-one years' experience as director of medical photography in a medical school in the U.S.A., may I offer brief comment on the several views expressed on this subject in the *British Medical Journal*? There is a world of difference between the terms progress and expansion I like to think of the word progress to mean "to develop to a higher stage," while the word expansion impresses me as meaning an act or process of growing Surely none of us could belittle the contributions advancing knowledge of photography has made to the field of medicine Can we dismiss with a wave of a hand improved techniques and such innovations as colour photography, infra-red, ultra-violet, phase microphotography, and photography with polarized light?

As is true in other fields, the pace of medical photography was accelerated in wartime The value of visual aids in the training of specialists was recognized by all Hence it follows that many of these aids and methods will and should be applied during peacetime Medical schools cannot function properly without these visual aids By the same token hospitals to day must become conscious of their responsibilities from the educational standpoint to both the doctor and the nurse Photographic records of the progressive or regressive changes in the patient's condition are not only necessary but in many instances have proved invaluable, legally and otherwise Pathological conferences and staff meetings are welcome and well attended by hospital staff members when the material presented is supplemented with good lantern slides or photographs Does not a well-posed informative photograph convey more convincing evidence than the words necessary to describe the subject photographed? Can anyone paint as clearly with words?

Progress of medical research with its discriminating application must go on and will reach its ultimate aim Medical photography must keep pace with this progress The development of the medical photographic department should be commensurate with the practical needs of the institution involved A department such as is mentioned by Dr Ff Roberts (March 13, p 485) in the paragraph headed 'The Fetish of Perpetual Expansion' is not a fair example of what constitutes the average medical photographic department I cannot conceive of such an elaborate arrangement in the face of present needs unless it would be in conjunction with some huge medical centre of the future

It is difficult to state just what constitutes the ideal medical photographic department The nature and scope of the research carried on in the institution and the extent of the programme of the educational department will influence the selection of the personnel and equipment and the planning of space Unreasonable demands upon the photographic department by staff members can be controlled I think we will find that the committee in control of policy, economy, and efficiency would exercise the same good judgment in the establishment and maintenance of a medical photographic department that it would manifest in other matters concerning the institution Medical photography cannot be denied and will go on contributing its share for the benefit of health It shall go forward parallel with progress in the field of medicine and medical research, regardless of the tone of ridicule permeating some of the expressions appearing in the *British Medical Journal*—I am, etc,

Marquette University School of Medicine  
Milwaukee Wisconsin

LEO C MASSOPUST

### Colonial Medical Service

SIR—I am entirely in agreement with the suggestions made by your correspondent "Imperialist" (Aug 7, p 314) As a native of British Guiana I can refer to the vital statistics and health conditions in this colony In my opinion British Guiana is one of the most unhealthy places within the Empire I base my conclusion on the following facts British Guiana has a higher birth rate than the United Kingdom, but the infant mortality rate is also much higher than in Great Britain Between 1835 and 1941, 333,803 immigrants were introduced

into the colony The total population in 1945 was 373,598 This means that over a period of 110 years the population had increased by only 11% Compare this with the 100% increase of population in Great Britain during the same period, despite two world wars

Plantation hospitals catering for thousands do not have resident doctors Plantation arcas do not have antenatal and child-welfare clinics, nor is there a midwifery service in these areas The majority of the population have to depend on unqualified persons employed in these places for the diagnosis and treatment of their diseases Women on the plantations have to bear their children without midwives or even pseudo midwives, and there have been instances of childbearing in the sugar-cane fields Children have to grow up in an entirely unhealthy and insanitary environment, without adequate nutrition

The Hon Cecil Clementi, a former Colonial Secretary of British Guiana, described the position adequately in the two following sentences, "Improved sanitation is the paramount need of the colony to-day," and, "The most pressing duty of the Government at the present time is to protect the health and lives of the existing population and to see that instead of the death rate exceeding the birth rate, as has too often been recorded in the vital statistics of British Guiana, there is a steady natural increment"—I am, etc,

GUIANESE

\*. This correspondence is now closed—ED *BMJ*

### POINTS FROM LETTERS

#### Nurses' Examination

Dr W EDGE (Salford, Lancs) writes Dr J H Weir (July 10, p 109) is quite right, the examiners often have no idea of the difficulties of nurses in digesting even the present syllabus, and there is no excuse for embarrassing them with completely irrelevant questions Hospitals have enough trouble in securing and teaching student nurses The lists of examiners should be overhauled Only teachers should be asked to examine nurses

#### Medical Illustrators

Miss ZITA M STEAD (19, York Avenue, East Sheen, London SW 14) writes I have received a letter from the Association of Medical Illustrators of America This association was formed in order to raise and guarantee a high standard of work from its members, and each member must be adequately trained and actively engaged in medical illustration The committee of the association would like to establish liaison with British artists, since they feel we could be of mutual help in many ways They therefore extend a warm invitation to all medical illustrators in the British Isles who are interested in this idea and would like to get in touch with them The treasurer's name and address is Elizabeth Brodel, the Lyng in Hospital 530, East 70th Street, New York, 21 I feel sure such an association would do much to improve the standard of medical illustration in this country, and I should be glad if any medical artist who is interested would please write to me

#### Smoking and Diet

Dr NEVIL LEYTON (London, W 1) writes During the war when most nervous systems were under stress increase in smoking was explained by its soothing effect But the habit has remained and one wonders why it has never been connected with post-war diet Reduction of fats from 75 g to under 40 g per day means that every one feels hungry sooner Smoking often relieves this sensation but the mechanism is not clear The same result may be achieved by the administration of amphetamine This substance and nicotine have similar properties in that they both cause an increase in gastric secretion and also raise the blood pressure, though just why either of these should reduce appetite is not obvious All the same, if the Minister of Food could supply more fats perhaps the demand for cigarettes would drop to pre-war proportions

#### Treatment of Pneumonia

Dr N WYNN WILLIAMS (Bedford) writes I agree with Dr Malcolm Tate (Aug 14, p 356) that all patients who have recently suffered from pneumonia should have a chest x-ray film taken However, his attention should be drawn to the fact that any modern tuberculosis dispensary (now usually and deliberately called chest clinic) will be only too willing to arrange such an x-ray examination for him Many cases of this type are referred to my clinic, and a considerable number of cases of pulmonary tuberculosis and other organic disease are diagnosed in this way We need not wait for health centres

## Obituary

### THOMAS GWYNNE MAITLAND, M.D., D.Phil

Dr Thomas Gwynne Maitland died suddenly at his home in Cheshire on Aug 10. He was medical superintendent of the Cunard White Star Company for twenty years. Born at Merthyr Tydfil in 1875, he was educated at University College School and at the Universities of Edinburgh, Manchester, and Paris. He graduated M.B., Ch.B. at Edinburgh University in 1907, and obtained his M.D. with distinction in 1908. He became a doctor of philosophy of Manchester University in 1911. His early experience was varied and unusual. At one time or other he was demonstrator in physiology at Manchester University, editor of the *Manchester Medical School Gazette*, lecturer in physiology at the Universities of Wales and Birmingham, honorary physician to Walsall General Hospital, lecturer on psychology at the Birmingham Midland Institute, and director of the typhus colony in Serbia during the first world war as a lieutenant-colonel in the Serbian Army. He contributed numerous papers to medical and psychological journals, and published in 1918 his *Examination of the Basis of Personality*. In 1920 he joined the Cunard Company and in 1926 was appointed its medical superintendent, a post for which he was pre-eminently suited by his rich experience and by natural aptitude and high technical ability. He retired in September, 1946.

From the beginning of his entry into this branch of occupational health his aim was to improve the lot of the merchant seaman, and the outstanding contribution to this end made by the Cunard White Star Company during recent years, with its resulting effect on conditions in the Merchant Navy as a whole, is due in great measure to Dr Maitland's personal influence. His interest took him beyond the sea and its peculiar hazards, however, and the allied problem of industrial disablement with its economic and social repercussions soon became to him an issue of the first magnitude. In this field his influence behind the scenes was great. It is little known, for instance, that he was one of those initially responsible for the setting up of the B.M.A. Committee on Fractures, whose report in 1935 heralded a new era in orthopaedic and accident surgery, that he was an international authority on workmen's compensation, or that he was a powerful influence in the formation of the policy of the Birmingham Accident Hospital several years before it opened in 1941. One keen ambition of his was to see founded an accident hospital in Liverpool, and to this end plans were continually in his mind. As far back as 1935 his conception of rehabilitation and his clear view of the need for new and comprehensive legislation as the only means of solving issues bound up with resettlement and workmen's compensation were well in advance of contemporary medical and sociological thought.

Dr Maitland had an unusual capacity for making and retaining friendships. To him this was no easy matter, but, his mind made up, he was a friend for life. He gave much. Behind the apparent physical frailty was a high courage, an obvious integrity, and a deep, consuming energy based on a passionate desire to help the underdog. He was modest to a fault and abhorred publicity. As a host he was beyond compare a supreme cosmopolitan. But perhaps his most appealing asset was his sense of humour, combined with an uncanny ability to debunk the pedant. It was not in him to suffer fools gladly, but he was essentially a man of gentleness and much understanding. To those whose privilege it was to come within his circle of friends his death means an irreplaceable loss. Medicine can ill afford to lose its philosophers, and Dr Maitland truly was one of them in high degree. His contribution to the welfare of seamen and disabled workers throughout the country acknowledged too little during his life largely because of his own wish now demands nothing less than the fullest recognition.—D.S.

Dr FRANCIS SUTHERLAND who died at his home in Edinburgh on Aug 14 at an untimely age was an unusual personality with experience of different sides of medical life. He graduated M.B., Ch.B. at Edinburgh in 1917 and took the D.Phil. three years later. His first appointment was concerned with

the investigation of an obscure outbreak of typhus which had occurred in Raasay, off the Isle of Skye. He was next appointed assistant county medical officer of health for that part of Inverness-shire which includes Skye, Harris, North and South Uist and Barra, perhaps the most difficult and thankless post in Great Britain. For ten years he travelled to and fro across the Minch in small steamers, inspected school-children, dealt with the inertia of Hebridean authorities, and struggled with the petty round of nuisances and small epidemics for which there was no hospital accommodation, no health-visiting, and no hygienic routine. In these difficult circumstances Francis Sutherland maintained a lofty standard of official procedure. He knew the law, he knew what was correct, and, using a typewriter, he constituted himself a one-man public health department and kept a voluminous correspondence unsurpassed by many who have a trained clerical staff. After a similar though less insular appointment in Ross-shire Sutherland decided to enter the field in which his father, Dr John F. Sutherland, had preceded him, that of administrative psychiatry. He opened a small residential clinic at Staines. But when the post which his father had held at the Scottish Board of Control fell vacant Francis Sutherland took the opportunity then offered him, and in 1936 he became deputy commissioner of the Board of Control for Scotland. This sphere of work, which exactly suited his temperament, so that once again he was journeying through the Highlands, occupied the last twelve years of his life. His broad figure in plus fours, cap, and a bow tie, became well known in Highland cottages and hotels. He always used great formality of language, indeed he spoke to patients—wards of the Board of Control—as physicians did a generation ago before modern slang was part of professional relationships. But he was always smiling, courteous, and helpful, and his human kindness showed itself to the last word of his official report. There was quality and style in all he did, and he never hurried never ignored details never allowed himself to be put off. When he had finished, the case was complete and unanswerable. In the evenings few could relax better, or tell more humorous stories about Scottish ministers, or quote classical poetry and prose with more point. Whenever he could, with Mrs Sutherland who survives him, he took a holiday on the Continent that was a sort of exploration, since beforehand in his usual thorough style he had studied the geography and the language. In this way he penetrated as far as the North Cape and studied the coast of Spain and Portugal. When he returned he had many good tales to tell. He was an unusual man who lived conscientiously and did his work unobtrusively, and, though he was not prominent in medicine his life expressed our best traditions.—H.W.

Dr HENRY RICHARD BELCHER HICKMAN, who died on July 8 at his home in Flax Bourton, Somerset was born on April 11, 1866 in London. His father Dr William Hickman, J.P. was physician-in-ordinary to H.R.H. the Duke of Saxe-Coburg. Henry Hickman was educated at Westminster School, Christ Church, Oxford, and St George's Hospital. He graduated at Oxford in 1894, and took the diplomas of M.R.C.S., L.R.C.P. in the same year. After working for some time in the pathological department at St George's he devoted himself to eye work, becoming a clinical assistant of the Royal Westminster Ophthalmic Hospital and ophthalmic surgeon at the Marylebone General Dispensary. He was one of the pioneers of school medical inspection in London, and for a time was assistant school medical officer under the Buckinghamshire County Council. In 1920 he came to Bristol University as lecturer in physiology and held this appointment until 1932. Dr Hickman was interested in wireless telegraphy from its earliest beginnings and had worked with Marconi. In 1911 he carried out some of the first tests on anti-dazzle head-lights for motor-cars. He was a keen photographer and delighted in colour photography. During his years at Oxford he was a first-class rifle shot and shot for his University against Cambridge. He was also an ardent Freemason and a past master of St Vincent Lodge (1404), Bristol. He married Miss Margaret Kate Thompson and they had two children—a son, who died in childhood and a daughter, Dr Rowena Margaret Hickman, who is now practising medicine in Somerset. To his widow and daughter we offer our deep sympathy.—J.A.N.

Dr STANLEY NINIAN WRIGHT senior assistant medical officer of health and school medical officer to Lancashire County Council, died on June 26 at the age of 58. He was a native of Liverpool, and was educated at Merchant Taylors' School, where he won a Harrison scholarship, a Lancashire County Council exhibition and many prizes. Proceeding to Liverpool University he continued to distinguish himself by winning many honours including the Robert Gee scholarship in medicine the Torr gold medal in anatomy, and a university exhibition in clinical medicine. Before graduating M.B., Ch.B. in 1912 he took a B.Sc. in physiology with first-class honours. After

the preservative Secondly, with regard to the presence of the accessory parotid gland, I should like to know in how many cases he looked for this part of the gland The article leads us to believe that it is an infrequent occurrence I have no figures to quote, but it is my opinion that careful examination would reveal it in at least a reasonably large percentage of cases—I am, etc,

### Medical Photography

SIR—With thirty-one years' experience as director of medical photography in a medical school in the USA, may I offer brief comment on the several views expressed on this subject in the *British Medical Journal*? There is a world of difference between the terms progress and expansion I like to think of the word progress to mean "to develop to a higher stage," while the word expansion impresses me as meaning an act or process of growing Surely none of us could belittle the contributions advancing knowledge of photography has made to the field of medicine Can we dismiss with a wave of a hand improved techniques and such innovations as colour photography, infra-red, ultra-violet, phase microphotography, and photography with polarized light?

As is true in other fields, the pace of medical photography was accelerated in wartime The value of visual aids in the training of specialists was recognized by all Hence it follows that many of these aids and methods will and should be applied during peacetime Medical schools cannot function properly without these visual aids By the same token hospitals to day must become conscious of their responsibilities from the educational standpoint to both the doctor and the nurse Photographic records of the progressive or regressive changes in the patient's condition are not only necessary but in many instances have proved invaluable, legally and otherwise Pathological conferences and staff meetings are welcome and well attended by hospital staff members when the material presented is supplemented with good lantern slides or photographs Does not a well-posed informative photograph convey more convincing evidence than the words necessary to describe the subject photographed? Can anyone paint as clearly with words?

Progress of medical research with its discriminating application must go on and will reach its ultimate aim Medical photography must keep pace with this progress The development of the medical photographic department should be commensurate with the practical needs of the institution involved A department such as is mentioned by Dr Ff Roberts (March 13, p 485) in the paragraph headed 'The Fetish of Perpetual Expansion' is not a fair example of what constitutes the average medical photographic department I cannot conceive of such an elaborate arrangement in the face of present needs unless it would be in conjunction with some huge medical centre of the future

It is difficult to state just what constitutes the ideal medical photographic department The nature and scope of the research carried on in the institution and the extent of the programme of the educational department will influence the selection of the personnel and equipment and the planning of space Unreasonable demands upon the photographic department by staff members can be controlled I think we will find that the committee in control of policy, economy, and efficiency would exercise the same good judgment in the establishment and maintenance of a medical photographic department that it would manifest in other matters concerning the institution Medical photography cannot be denied and will go on contributing its share for the benefit of health It shall go forward parallel with progress in the field of medicine and medical research, regardless of the tone of ridicule permeating some of the expressions appearing in the *British Medical Journal*—I am, etc,

Marquette University School of Medicine

LEO C MASSOPUST

### Colonial Medical Service

SIR—I am entirely in agreement with the suggestions made by your correspondent "Imperialist" (Aug 7, p 314) As a native of British Guiana I can refer to the vital statistics and health conditions in this colony In my opinion British Guiana is one of the most unhealthy places within the Empire I base my conclusion on the following facts British Guiana has a higher birth rate than the United Kingdom, but the infant mortality rate is also much higher than in Great Britain Between 1835 and 1941, 333,803 immigrants were introduced

into the colony The total population in 1945 was 373,598 This means that over a period of 110 years the population had increased by only 11% Compare this with the 100% increase of population in Great Britain during the same period, despite, two world wars

Plantation hospitals catering for thousands do not have resident doctors Plantation areas do not have antenatal and child-welfare clinics, nor is there a midwifery service in these areas The majority of the population have to depend on unqualified persons employed in these places for the diagnosis and treatment of their diseases Women on the plantations have to bear their children without midwives or even pseudo midwives, and there have been instances of childbearing in the sugar cane fields Children have to grow up in an entirely unhealthy and insanitary environment, without adequate nutrition

The Hon Cecil Clementi, a former Colonial Secretary of British Guiana, described the position adequately in the two following sentences, "Improved sanitation is the paramount need of the colony to-day," and, "The most pressing duty of the Government at the present time is to protect the health and lives of the existing population and to see that instead of the death rate exceeding the birth rate, as has too often been recorded in the vital statistics of British Guiana, there is a steady natural increment"—I am, etc,

GUIANESE

### POINTS FROM LETTERS

#### Nurses' Examination

Dr W EDGE (Salford, Lancs) writes Dr J H Weir (July 10, p 109) is quite right, the examiners often have no idea of the difficulties of nurses in digesting even the present syllabus, and there is no excuse for embarrassing them with completely irrelevant questions Hospitals have enough trouble in securing and teaching student nurses The lists of examiners should be overhauled Only teachers should be asked to examine nurses

#### Medical Illustrators

MISS ZITA M STEAD (19, York Avenue, East Sheen, London, SW 14) writes I have received a letter from the Association of Medical Illustrators of America This association was formed in order to raise and guarantee a high standard of work from its members, and each member must be adequately trained and actively engaged in medical illustration The committee of the association would like to establish liaison with British artists, since they feel we could be of mutual help in many ways They therefore extend a warm invitation to all medical illustrators in the British Isles who are interested in this idea and would like to get in touch with them The treasurer's name and address is Elizabeth Brodel, the Lying in Hospital, 530, East 70th Street, New York, 21 I feel sure such an association would do much to improve the standard of medical illustration in this country, and I should be glad if any medical artist who is interested would please write to me

#### Smoking and Diet

Dr NEVIL LEYTON (London, W 1) writes During the war when most nervous systems were under stress increase in smoking was explained by its soothing effect But the habit has remained and one wonders why it has never been connected with post-war diet Reduction of fats from 75 g to under 40 g per day means that every one feels hungry sooner Smoking often relieves this sensation, but the mechanism is not clear The same result may be achieved by the administration of amphetamine This substance and nicotine have similar properties in that they both cause an increase in gastric secretion and also raise the blood pressure, though just why either of these should reduce appetite is not obvious All the same, if the Minister of Food could supply more fats perhaps the demand for cigarettes would drop to pre war proportions

#### Treatment of Pneumonia

Dr N WYNN-WILLIAMS (Bedford) writes I agree with Dr Malcolm Tate (Aug 14, p 356) that all patients who have recently suffered from pneumonia should have a chest x-ray film taken However, his attention should be drawn to the fact that any modern tuberculosis dispensary (now usually and deliberately called chest clinic) will be only too willing to arrange such an x-ray examination for him Many cases of this type are referred to my clinic, and a considerable number of cases of pulmonary tuberculosis and other organic disease are diagnosed in this way We need not wait for health centres

## Obituary

### THOMAS GWYNNE MAITLAND, M.D., D.Phil.

Dr Thomas Gwynne Maitland died suddenly at his home in Cheshire on Aug 10. He was medical superintendent of the Cunard White Star Company for twenty years. Born at Merthyr Tydfil in 1875 he was educated at University College School and at the Universities of Edinburgh, Manchester and Paris. He graduated M.B., Ch.B. at Edinburgh University in 1907, and obtained his M.D. with distinction in 1908. He became a doctor of philosophy of Manchester University in 1911. His early experience was varied and unusual. At one time or other he was demonstrator in physiology at Manchester University, editor of the *Manchester Medical School Gazette*, lecturer in physiology at the Universities of Wales and Birmingham, honorary physician to Walkill General Hospital, lecturer on psychology at the Birmingham Midland Institute and director of the typhus colony in Serbia during the first world war as a lieutenant-colonel in the Serbian Army. He contributed numerous papers to medical and psychological journals and published in 1918 his *Examination of the Basis of Personality*. In 1920 he joined the Cunard Company and in 1926 was appointed its medical superintendent, a post for which he was pre-eminently suited by his rich experience and by natural aptitude and high technical ability. He retired in September 1946.

From the beginning of his entry into this branch of occupational health his aim was to improve the lot of the merchant seaman, and the outstanding contribution to this end made by the Cunard White Star Company during recent years, with its resulting effect on conditions in the Merchant Navy as a whole, is due in great measure to Dr Maitland's personal influence. His interest took him beyond the sea and its peculiar hazards, however, and the allied problem of industrial disablement with its economic and social repercussions soon became to him an issue of the first magnitude. In this field his influence behind the scenes was great. It is little known for instance that he was one of those initially responsible for the setting up of the B.M.A. Committee on Fractures, whose report in 1935 heralded a new era in orthopaedic and accident surgery, that he was an international authority on workmen's compensation, or that he was a powerful influence in the formation of the policy of the Birmingham Accident Hospital several years before it opened in 1941. One keen ambition of his was to see founded an accident hospital in Liverpool, and to this end plans were continually in his mind. As far back as 1935 his conception of rehabilitation and his clear view of the need for new and comprehensive legislation as the only means of solving issues bound up with resettlement and workmen's compensation were well in advance of contemporary medical and sociological thought.

Dr Maitland had an unusual capacity for making and retaining friendships. To him this was no easy matter, but his mind made up, he was a friend for life. He gave much. Behind the apparent physical frailty was a high courage, an obvious integrity and a deep, consuming energy based on a passionate desire to help the underdog. He was modest to a fault and abhorred publicity. As a host he was beyond compare, a supreme cosmopolitan. But perhaps his most appealing asset was his sense of humour, combined with an uncanny ability to debunk the pedant. It was not in him to suffer fools gladly, but he was essentially a man of gentleness and much understanding. To those whose privilege it was to come within his circle of friends his death means an irreparable loss. Medicine can ill afford to lose its philosophers, and Dr Maitland truly was one of them in high degree. His contribution to the welfare of seamen and disabled workers throughout the country, acknowledged too little during his life largely because of his own wish, now demands nothing less than the fullest recognition.—D.S.

Dr FRANCIS SUTHERLAND, who died at his home in Edinburgh on Aug 14 at an untimely age was an unusual personality with experience of different sides of medical life. He graduated M.B., Ch.B. at Edinburgh in 1917, and took the D.P.H. three years later. His first appointment was concerned with

the investigation of an obscure outbreak of typhus which had occurred in Barra off the Isle of Skye. He was next appointed assistant county medical officer of health for that part of Inverness shire which includes Skye, Harris, North and South Uist and Barra, perhaps the most difficult and thankless post in Great Britain. For ten years he travelled to and fro across the Minch in small steamers, inspected school children, dealt with the inertia of Hebridean authorities and struggled with the petty round of nuisances and small epidemics for which there was no hospital accommodation, no health visiting, and no hygienic routine. In these difficult circumstances Francis Sutherland maintained a lofty standard of official procedure. He knew the law, he knew what was correct and using a typewriter he constituted himself a one man public health department and kept a voluminous correspondence unsurpassed by many who have a trained clerical staff. After a similar though less insular appointment in Ross-shire Sutherland decided to enter the field in which his father Dr John F. Sutherland had preceded him, that of administrative psychiatry. He opened a small residential clinic at Staines. But when the post which his father had held at the Scottish Board of Control fell vacant Francis Sutherland took the opportunity then offered him, and in 1936 he became deputy commissioner of the Board of Control for Scotland. This sphere of work which exactly suited his temperament so that once again he was journeying through the Highlands occupied the last twelve years of his life. His broad face, in plus four cap and a bow tie became well known in Highland cottages and hotels. He always used great formality of language, indeed he spoke to patients—wards of the Board of Control—as physicians did a generation ago, before modern slang was part of professional relationships. But he was always smiling, courteous and helpful and his human kindness showed itself to the last word of his official report. There was quality and style in all he did and he never hurried, never ignored details, never allowed himself to be put off. When he had finished the case was complete and unanswerable. In the evenings few could relax better or tell more humorous stories about Scottish ministers or quote classical poetry and prose with more point. Whenever he could with Mrs Sutherland who survives him he took a holiday on the Continent that was a sort of exploration since beforehand in his usual thorough style he had studied the geography and the language. In this way he penetrated as far as the North Cape and studied the coast of Spain and Portugal. When he returned he had many good tales to tell. He was an unusual man who lived conscientiously and did his work unobtrusively and though he was not prominent in medicine his life expressed our best traditions.—H.W.

Dr HENRY RICHARD BEECHER HICKMAN, who died on July 8 at his home in Hilly Bourton, Somerset, was born on April 11, 1866 in London. His father Dr William Hickman, J.P., was physician in ordinary to H.R.H. the Duke of Saxe-Coburg. Henry Hickman was educated at Westminster School, Christ Church, Oxford, and St George's Hospital. He graduated at Oxford in 1894 and took the diplomas of M.R.C.S., L.R.C.P. in the same year. After working for some time in the pathological department at St George's he devoted himself to eye work, becoming a clinical assistant of the Royal Westminster Ophthalmic Hospital and ophthalmic surgeon at the Marylebone General Dispensary. He was one of the pioneers of school medical inspection in London, and for a time was assistant school medical officer under the Buckinghamshire County Council. In 1920 he came to Bristol University as lecturer in physiology and held this appointment until 1932. Dr Hickman was interested in wireless telegraphy from its earliest beginnings and had worked with Marconi. In 1911 he carried out some of the first tests on anti-dazzle head-lights for motor-cars. He was a keen photographer and delighted in colour photography. During his years at Oxford he was a first-class rifle shot and shot for his University against Cambridge. He was also an ardent Freemason and a past master of St Vincent Lodge (1404) Bristol. He married Miss Margaret Kate Thompson and they had two children, a son, who died in childhood, and a daughter, Dr Rowena Margaret Hickman, who is now practising medicine in Somerset. To his widow and daughter we offer our deep sympathy.—J.A.N.

Dr STANLEY NINIAN WRIGHT, senior assistant medical officer of health and school medical officer to Lancashire County Council, died on June 26 at the age of 58. He was a native of Liverpool, and was educated at Merchant Taylors' School where he won a Harrison scholarship, a Lancashire County Council exhibition and many prizes. Proceeding to Liverpool University he continued to distinguish himself by winning many honours, including the Robert Gee scholarship in medicine, the Torr gold medal in anatomy, and a university exhibition in clinical medicine. Before graduating M.B., Ch.B. in 1912 he took a B.Sc. in physiology with first class honours. After

spending eighteen months in various resident posts in the Liverpool Royal Infirmary and City Hospital, Dr Wright obtained his MSc in 1914, and a few months later the DPH. The years 1914 to 1919 were devoted to war service, first for a few months in the Army, then as a temporary surgeon-lieutenant in the Royal Navy. Much of his time was spent as resident medical officer to the Royal Naval College, Osborne. Immediately following demobilization in 1919 he became assistant port medical officer to the Liverpool port sanitary authority, a post which he held until June, 1920, when he was appointed to the medical staff of the Lancashire County Council, on which he served until his death. Whatever Stanley Wright did he did with all his heart, whether it was in connexion with his professional work or in the realm of sport, in which he excelled. His successes in academic life were paralleled on the rugby football field and later on the golf course, where he played from scratch and represented his county. His leisure moments he devoted to literature and the appreciation of music. Representative of the very best type of medical man, courteous in approach, skilful in ministrations, and of an unfailing human kindness, he will not be forgotten by his friends and colleagues, or by the folk among whom he worked for so many years in Haydock and Prescott. He is survived by his widow and a daughter.

Dr HENRY DOYLE BRICE died at the home of his younger daughter in Dewsbury on Aug 7, at the age of 74, after a long and distressing illness. Born in the Channel Islands, he first qualified as a chemist, which enabled him to pay his way through his medical training. He was a student of Westminster Hospital, and won the Frederick Bird medal in midwifery and qualified MRCS, LRCP in 1900. He started his medical career as a general practitioner in Chelsea, and was soon appointed medical officer to the district and out-patient department of Chelsea Infirmary, medical officer to the Chelsea Distress Committee, and a lecturer in midwifery under the Midwives Board. These appointments he held until he moved to Dukinfield, Cheshire, in 1908, where he proceeded to build up a large practice. Dr Brice was appointed assistant radiologist to the Ashton-under-Lyne and District Infirmary in 1919. His work in general practice gave him an insight into the needs of the poor, and in an endeavour to improve their lot in life he consented to be nominated as a candidate for the Dukinfield borough council. He was elected in 1922 and served on the council for 26 years, becoming an alderman in 1939 and acting as mayor of the town in 1932. Dr Brice was also elected to the Cheshire County Council in 1925, and later became a county alderman. On both borough and county councils he interested himself particularly in housing and in maternity work. Dr Brice was always an active member of the British Medical Association, and he was chairman of the Hyde Division for over ten years. He married in 1904, and his wife, formerly Miss Judson, helped him in all his work until she died in 1938. He leaves two daughters and a son, all members of the medical profession.

## Medico-Legal

### MENINGITIS FOLLOWING SPINAL ANAESTHESIA

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

In April, 1947, the High Court awarded damages of £12,000 against the Portsmouth Corporation to a young man who contracted meningitis after a spinal injection of "nupercaine" and was left with permanent paralysis of both legs and incontinence of urine.<sup>1</sup> Actions against the practitioners concerned failed. The corporation appealed, and counsel maintained that the trial judge, Mr Justice Birkett, had disregarded evidence that the infection with *Ps. pyocyanea* could have been caused in spite of all proper precautions to prevent it.

Lord Justice Bucknill, giving the judgment of the Court of Appeal,<sup>2</sup> said that there was sufficient evidence that the patient's injury was directly due to an injection of "nupercaine" into his spinal canal. This had introduced a bacillus which had caused the meningitis, and the cause of the disease was negligence and breach of duty by the corporation's servants in failing to carry out proper aseptic precautions. There was no satisfactory evidence that the syringe had been sterilized in accordance with the usual practice obtaining in the hospital in 1944. The appeal was therefore dismissed.

## Universities and Colleges

### UNIVERSITY OF OXFORD

In a Congregation held on July 31 the following degrees were conferred

DM—G I M Swyer  
MCh—\*G O Jelly  
BM—R A Bruce J P Horder, W G H Leslie M C Manifold D Razzak  
C G A Thomas H W James A W Lindsay M G M Venables W H Taylor D P Winstanley, N S C Gent F D Kelsey J R Sudbury, F J C Roe L Bagratuni G E S Jones, D R Richard Katharine M S Ainley Walker Barbara E Porritt \*D F Magee, \*H Ellis \*J E Cotes, \*P D Wall \*P Harrison Hall \*M A Peyman \*J Swinbank \*B L Day, \*J N Micklethorp  
\* In absence

### UNIVERSITY OF LONDON

Sir Francis Fraser, Director of the British Postgraduate Medical Federation, has been reappointed Deputy Vice-Chancellor for 1948-9.

On the occasion of the Congress of the Universities of the Empire, held at Oxford from July 19 to 23, the honorary degree of LL.D. was conferred on James Bertram Collip, CBE, FRS, Professor of Medical Research and Dean of the Faculty of Medicine at the University of Western Ontario, among others, at a ceremony held at Senate House, London, W.C., on July 17.

The following members of the medical profession have been appointed representatives of the University on the governing bodies of the institutions indicated in parentheses: Sir Archibald Gray and Mr J B Hunter (British Postgraduate Medical Federation, and, for the first year, School of Pharmacy), Dr D H Brinton (Charing Cross Hospital Medical School), Professor S J Cowell and Professor Esther M Killick (King's College of Household and Social Science), Dr A E Clark-Kennedy (Queen Mary College), Mr J B Hunter (Royal Free Hospital School of Medicine), and Professor J M Mackintosh (Slough Industrial Health Service, Ltd).

The following have been recognized as teachers of the University in the subjects indicated in parentheses: *St Bartholomew's Hospital Medical College* Dr R Bodley Scott (Medicine), *St Mary's Hospital Medical School* Dr M H E Hulbert (Radiology), *London Hospital Medical College* Dr J H T Challis (Anaesthetics), Mr C A Keogh (Oto-rhino-laryngology), Mr W A Law (Orthopaedics), Dr H B May (Pathology), Mr R C Percival (Obstetrics and Gynaecology), *St Thomas's Hospital Medical School* Mr R B K Rickford (Obstetrics and Gynaecology), *Charing Cross Hospital Medical School* Dr H K Ashworth (Anaesthetics), Dr A Doynne C Bell (Children's Diseases), Dr F A Elliott (Medicine), Dr D P King (Clinical Pathology), *Westminster Hospital Medical School* Mr F A d'Abreu (Surgery), Dr C J Garvey (Medicine), *University College Hospital Medical School* Dr H A Burt (Physical Medicine), *King's College Hospital Medical School* Mr S G Clayton (Obstetrics and Gynaecology), Mr Ralph Cocker, MB, ChB, FDS (Dental Surgery), Dr A C Cunliffe (Bacteriology), Dr R D Lawrence and Dr S Oram (Medicine), Dr D I Williams (Venereal Diseases), Mr A J Heriot (Surgery, probationary), *Maudsley Hospital* Dr E W Anderson (Psychiatry).

The Diploma in Medical Radiology has been replaced by a Diploma in Medical Radiology (Radiodiagnosis) and a Diploma in Medical Radiology (Therapy). The regulations for these diplomas have been approved and copies may be obtained from the Academic Registrar of the University at Senate House, London, W.C.1.

The Worcester Royal Infirmary has been recognized for the purposes of the Diploma in Clinical Pathology for a period of five years from September, 1948.

### UNIVERSITY OF LEEDS

Professor James W McLeod, FRS, Brotherton Professor of Bacteriology at Leeds University since 1922, has been appointed Dean of the Medical Faculty of the University in succession to Professor M J Stewart, who is retiring owing to the pressure of other work.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

Sir Hugh Cairns, Nuffield Professor of Surgery in the University of Oxford, left this country on Aug 3 to visit the principal medical centres in South Africa as the first Arthur Sims Travelling Professor. He will deliver lectures, make contact with leading scientists, and take part in research and postgraduate teaching. Sir Hugh Cairns arrived at Johannesburg on Aug 13, at Durban on Aug 27, and is due at Capetown on Sept 1. He recently returned from a somewhat similar trip to Australia and New Zealand.

It is confidently hoped that the institution of this travelling professorship will not only do much to stimulate the development of medical science for the benefit of mankind but that it will also prove a further valuable link between the nations of the Commonwealth.

## Medical News

### Alvarenga Prize

In recognition of his studies on sludged blood the College of Physicians of Philadelphia awarded on July 14 the Alvarenga Prize for 1948 to Melvin H. Knisely, M.D., of the University of Chicago. The Alvarenga Prize was established by the will of Pedro Francisco da Costa Alvarenga, of Lisbon, Portugal, an Associate Fellow of the College of Physicians of Philadelphia, "to be awarded annually by the College of Physicians on each anniversary of the death of the testator, July 14, 1883." The College usually makes this award for outstanding work and invites the recipient to deliver an Alvarenga Lecture before the College.

### Foreign Medical Scholarships

Scholarships for study abroad have been awarded to five post graduate medical students through the British Council. The Belgian Government has awarded a four months' scholarship in tropical medicine to Dr. H. F. Lyon (University of Edinburgh), and another in dermatology to Dr. R. P. Warn (University of Leeds). The Government of Sweden and the Swedish Institute are the donors of a further two four month scholarships in surgery and medicine, these have been awarded respectively to Dr. C. Dafoe (Queen's University, Ontario) and Dr. J. Scott Baker (University of London). Miss L. Hodgson (University of Leeds) is the recipient of a nine months scholarship in ophthalmology awarded by the Netherlands Government. The British Council has this year been asked by the governments or universities of nine foreign countries to obtain candidates and make recommendations for some 40 scholarships. Successful candidates are selected as the result of recommendations made by the British Council's Universities Advisory Committee to the country or university concerned.

### Quarantine Measure Rescinded

The following Quarantine Notification, No. 15 of 1948, dated July 1, has been issued by the Director, Shanghai Quarantine Service. In accordance with the decision of the WHO Expert Committee on International Epidemic Control on April 17, 1948, and Expert Committee on Quarantine on Oct. 16, 1947, in regard to rescinding of vaccination against plague or typhus as an international quarantine measure, the public is hereby notified that travellers arriving at or departing from plague or typhus infected ports are not required to produce evidence of vaccination against these diseases.

### Boards of Governors

Since the publication of the names of the members of the Boards of Governors of Teaching Hospitals (London) in our issue of June 26 (p. 1250), the Ministry of Health has announced that Sir T. Drummond Shiels has been appointed to the Board of the Hammer Smith, West London, and St. Mark's Hospitals.

### Enzyme Study Award

Dr. Albert L. Lehninger, assistant professor of biochemistry at the University of Chicago, has received the \$1,000 Paul-Lewis Laboratory award in enzyme chemistry for his work on the chemistry and metabolism of the fatty acids.

### Dentists in the Service

The Ministry of Health states that up to Aug. 7 the number of dentists in England and Wales who had entered the National Health Service was 6,654, out of an estimated total of about 10,000 dentists in general practice.

### Waste Straw

Under this heading last week (p. 406) we published a note to the effect that Professor S. Zuckerman, of Birmingham University, had been appointed head of a Government committee to find a use for waste straw. This information was taken from a report in the Press which we now learn is quite inaccurate.

### New School for Spastics

A special school for the reception of children suffering from spastic paralysis is to be opened in Edinburgh next month by the Scottish Council for the Care of Spastics. The house which is to be used was bought recently by the Scottish Branch of the British Red Cross Society.

### Hospital Contributory Schemes

Up to July 1 thirty hospital contributory schemes have notified the British Hospitals Contributory Schemes Association that they will continue to operate for the provision of benefits ancillary and additional to those provided under the National Health Service Act.

### Diphtheria Antitoxin

Emergency stocks of diphtheria antitoxin were in the past commonly held by local authorities' health departments. The power to provide antitoxin was repealed by the National Health Service Act. A few pharmacists hold stocks, but their number is insufficient for all medical practitioners to be able to obtain antitoxin quickly in emergency. Hospitals for infectious diseases also hold stocks, but they are not always conveniently accessible, and the Minister of Health is therefore arranging with boards of governors and hospital management committees for a small stock of antitoxin to be held at a convenient general hospital in any centre of population which does not include a readily accessible hospital for infectious diseases. Executive councils will be notified by the regional hospital boards of the places where the antitoxin will be available.

### Hospital Equipment Standards Advisory Committee

The first report of the Hospital Equipment Standards Advisory Committee of the British Standards Institution gives the history of the formation of the Committee, its terms of reference, and a list of the organizations that are represented upon it. The Committee was formed early in 1947 to investigate the need and to make recommendations for the preparation of British Standards for articles of hospital equipment. The report contains an indication of the subjects under consideration, together with notes regarding future activity. It can be obtained from the British Standards Institution Sales Department, 24, Victoria Street, SW 1, price 6d, post free.

## COMING EVENTS

### Association of Medical Records Officers

Week end training courses for records officers will be held at Cardiff Royal Infirmary, for the Welsh Region, on Sept. 4 and 5, and at the Royal Free Hospital, Gray's Inn Road, London, W.C., for the North-West Metropolitan Region, on Sept. 11 and 12. Interested hospitals in these regions should write to the records officer at the hospital concerned.

### London County Medical Society

A meeting of the London County Medical Society will be held at Joyce Green Hospital, Dartford, Kent, on Thursday, Sept. 9, at 3 p.m.

## APPOINTMENTS

DEWELL MARY W. Temporary Medical Officer to Prudhoe-on-Tyne District Northumberland.

MAYES JOYCE B. M., Assistant Medical Officer of Health for West Suffolk County Council and Assistant School Medical Officer and District Medical Officer of Health for Sudbury Borough, Hadleigh and Melford Rural Districts.

ROYAL NORTHERN HOSPITAL, Holloway, London, N.—Physician to Neurological Department: E. C. O. Jewell, M.D., M.R.C.P., D.P.M. Physician to Psychiatric Department: B. Buckley Sharp, M.D., M.R.C.P., D.P.M. W. Lindsey Neussalter, M.D., M.R.C.P.

TELLING MAXWELL, D.M., M.R.C.P. Honorary Assistant Physician, General Infirmary at Leeds.

THORBURN A. L. M.D., D.P.H. Full-time Divisional Medical Officer, School Medical Officer and District Medical Officer for Norwich City.

## BIRTHS, MARRIAGES, AND DEATHS

### BIRTH

Price.—On Aug. 9, 1948, to Barbara, wife of Dr. A. E. Kingsley Price of 36 St. John Hill, Bath: a son.

### MARRIAGES

Boyle-Smith.—On Aug. 19, 1948, at South Bank, Middlesbrough: Philip Terence Boyle, M.B., B.Ch., of Linton, Wetherby, to Dorothy Smith of South Bank, Middlesbrough.

Thomas-Kemp.—On June 19, 1948, at St. Margaret's Church, Warrnambool: Trevor Meyrick Thomas, M.Ch., F.R.C.S., son of the late Dr. and Mrs. J. E. Thomas of Bingley, to Judith Margaret, youngest daughter of the late Dr. J. H. Kemp of Horsham and of Mrs. Kemp.

### DEATHS

Bell.—On Aug. 13, 1948, at Ploverfield, Ben Rhydding, Yorks: John James Bell, F.R.C.S.I., F.R.C.S.Ed.

Billings.—On July 30, 1948, at Rocky Bank, Norton Road, Bourne, Cambs: Alfred Mearns Billings, L.R.C.P.S. Ed., L.R.F.P.S. Glas.

Forrester.—On Aug. 13, 1948, in Ireland: Archibald Thomas William Forrester, M.D.

Hayes.—Recently: Francis Xavier Hendellan Hayes, L.R.C.P.S. Ed., L.R.F.P.S. Glas.

Hood.—On Aug. 16, 1948, at Howe Hill, Acorn Road, York: Noel Lockwood Hood, M.D., aged 77.

Hunter.—Recently: Samuel Robert Hunter, M.D.

Jameson.—Recently: James Conway Jameson, M.B., C.M. Ed., D.P.H.

McCauley.—Recently at Ashdene, Omagh, Co. Tyrone: James Edward McCauley, M.B., B.Ch., aged 49.

Nesbitt.—Recently at Allesbury Road, Dublin: George Edward Nesbitt, M.D., F.R.C.P.I., aged 66.

O Byrne.—Recently: Conor O Byrne, M.B., B.Ch.

Sankarallil.—On June 22, 1948, Esau Jymsted Sankarallil, M.D., D.P.H. of Trinidad, B.W.I.

Welsh.—Recently: William John Wainock Welsh, M.B., Ch.B.

Willett.—Recently: James Hayward Willett, M.D., F.R.C.O.G.

Wilson.—On Aug. 13, 1948, at Old Bennington, Vermont, U.S.A.: John Gordon Wilson, M.B., C.M., aged 89.

No 32

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug 7

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) Scotland (d) Eire (e) Northern Ireland  
Deaths recorded under each infectious disease in England and Wales (including London)  
(b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland  
A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	40	2	20	3	—	66	6	32	2	3
Diphtheria Deaths	107	13	28	6	—	138	9	48	10	8
Dysentery Deaths	111	12	30	—	—	78	10	16	—	—
Encephalitis lethargica Deaths	—	—	2	—	—	1	—	—	—	—

Polio encephalitis acute Deaths	116	17	113	21	6	9	128	18	3	—
Poliomyelitis acute Deaths§	38	3	4	2	5	568	84	93	6	33
Puerperal fever Deaths	—	—	10	—	—	1	16	—	—	—
Puerperal pyrexia   Deaths	135	10	7	—	—	103	6	11	—	—
Relapsing fever Deaths	—	—	—	—	—	1	1	—	—	—
Scarlet fever Deaths†	848	49	134	29	21	680	61	114	18	19
Smallpox Deaths	—	—	—	—	—	—	—	—	—	—
Typhoid fever Deaths	10	—	—	4	—	9	—	1	1	4
Typhus fever Deaths	—	—	—	—	—	—	—	—	—	—
Whooping cough* Deaths	3,185	263	11	79	12	1,508	156	51	52	3
Deaths (0-1 year) Infant mortality rate (per 1 000 live births)	249	41	40	—	9	295	44	64	13	15
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	3 586	584	517	—	84	3 603	562	475	143	89
Live births Annual rate per 1 000 persons living	7 586	1242	939	—	242	8 385	1347	1096	465	246
Stillbirths Rate per 1 000 total births (including stillborn)	161	19	31	—	—	215	25	32	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

† Deaths from measles and scarlet fever for England and Wales (London (administrative county) will no longer be published

‡ Includes primary form for England and Wales, London (administrative county) and Northern Ireland

§ The number of deaths from poliomyelitis and polio encephalitis for England and Wales (London (administrative county) and Northern Ireland) are combined

|| Includes deaths from puerperal fever and puerperal pyrexia for England and Wales (London (administrative county) and Northern Ireland) are combined  
The returns received ended Aug 7 has not been received

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis

Preliminary figures of notifications of poliomyelitis for the week ended Aug 21 suggest that the final figures for that week are likely to be 70 to 75 as against a level of 35 to 40 for the last few weeks. A seasonal rise was to be expected and has often occurred in past years at about this time. It will be recalled that last year the rise began very much earlier, in the week ended June 7, 1947

## Discussion of Table

In England and Wales there were 1,332 fewer notifications of measles than in the previous week, and decreases were also reported for scarlet fever 481, whooping-cough 124, and diphtheria 18. The notifications of dysentery numbered 111, an increase of 34 on the week ending July 31

The largest falls in the notifications of measles during the week occurred in Lancashire 166, Warwickshire 151, Surrey 84, and Kent 81. Very few counties reported increases, the largest were Hertfordshire 38, Cornwall 37, and Cumberland 35

The decline in the incidence of scarlet fever was fairly general, the greatest fall was reported in the West Riding of Yorkshire, where 65 fewer notifications were made than in the previous week. The greatest changes in the notifications of whooping-cough were decreases of 58 in Cheshire, 36 in Sussex, and 35 in Gloucestershire and there were increases of 38 in Leicestershire and 24 in Derbyshire and Durham

Cheshire and Lancashire reported 12 and 8 fewer cases of diphtheria, respectively, other fluctuations in the notifications of this disease were relatively unimportant

The increase in the notifications of dysentery arose mainly from the experience of Warwickshire and Lancashire, 29 and 37 notifications were made, respectively, representing increases on the previous week of 22 and 26. Of the 29 notifications in Warwickshire, 27 were reported from Warwick R.D., while of the 37 cases reported from Lancashire, Preston C.B. was responsible for 23, Liverpool C.B. for 6, and Lancaster M.B. for 5. Notifications of paratyphoid fever numbered 47, of which 27 were reported from Eastbourne C.B.

There were 38 notifications of acute poliomyelitis during the week in the country as a whole. Of the county boroughs only Bristol and Birmingham reported more than one case each had 2. The following counties had more than one notification each: West Riding of Yorkshire 4, Lancashire, London and Warwickshire 3 each, Durham, Essex, Gloucester, Kent, Middlesex, Oxfordshire, Surrey, and Wiltshire 2 each

In Scotland there were 74 fewer notifications of scarlet fever, but apart from this, changes from the previous week were slight

In Eire a decrease in the number of notifications was reported for measles 41 and scarlet fever 35. There were 43 cases of infective enteritis or diarrhoea under 2 years of age, an increase of 25 largely attributable to Dublin, where there were 16 more notifications than in the previous week

In Northern Ireland the notifications of measles fell by 17

## Week Ending August 14

The notifications of infectious diseases in England and Wales during the week included scarlet fever 774, whooping cough 3,458, diphtheria 106, measles 5,897, acute pneumonia 282, cerebrospinal fever 38, acute poliomyelitis 37, dysentery 107, paratyphoid 19, and typhoid 8

In the Report of the Departmental Committee on Greater London Water Supplies (London H.M.S.O. Price 3s 6d) attention is drawn to the serious danger of water shortage in London if consumption continues to rise. The committee considers that a full and exhaustive inquiry should be made urgently into water resources and prospective demands throughout the area. Simultaneously plans should be prepared for a new major source of supply, which the report states will undoubtedly be needed in the not very distant future. The committee were of the opinion that it is in the interests of public health that the consumption of water should increase (due regard being paid to the avoidance of waste), and they estimate that the eventual daily consumption per head may be 60 gallons in the Metropolitan Water Board's area and 50 gallons in the surrounding area. There were differences of opinion about the best method of administering London's water supply. Two members of the committee (including the chairman) considered that a single all-purpose authority, with full executive powers over both supply and distribution, should be established. On the other hand, three members, while agreeing that a central water authority to control all sources of supply in the area should be appointed, suggested in addition the establishment of four independent joint water boards for the distribution of water. The area suggested by the Metropolitan Water Board is suitable for administration by a single authority has a population of over 10,000,000 people and is at present served by 64 independent water undertakings

# The answer everywhere

## to IRON DEFICIENCY ANAEMIA

Ask a doctor in India in Australia in Argentina anywhere, which condition he meets most often as a result of nutritional defect. Almost always his reply will be *iron deficiency anaemia*. Here is one international problem for which there is a unanimous answer—the simple administration of iron by mouth. This is the single clear-cut purpose of Fersolate Tablets, the original preparation of ferrous sulphate combined with copper and manganese.

Even the severest case normally responds to the recom-

mened dose of three Fersolate Tablets daily, haemoglobin regeneration occurring at the rate of 1 to 2 per cent daily. And quite apart from the specific action of Fersolate, this simple routine often brings dramatic improvement in the patient's general well-being.

GLAXO

**FERSOLATE TABLETS**

Known as Fersolin in certain countries

In containers of 100

Each tablet contains exsiccated ferrous sulphate 3 grains (200 mg.) copper sulphate 1/25 grain (2.5 mg.) manganese sulphate 1/25 grain (2.5 mg.)

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX, ENGLAND

Other laboratories and factories in England at Barnard Castle, Driffield, Stratford (London E 15) and Ulverston. In Argentina, India, Italy and New Zealand. Agents in almost every country in the world.

## BRONCHIAL ASTHMA

The effect upon the bronchial musculature is among the selective mechanisms of action of the drug Cardophylin. It appears that the seat of its bronchial antispasmodic action is peripheral and due to direct depression of bronchial smooth muscle.

### Cardophylin

THEOPHYLLINE ETHYLENEDIAMINE

**INDICATIONS**

## SULPHACETAMIDE IN OPHTHALMOLOGY

The sodium salt of Sulphacetamide is particularly useful for local application to the eyes.

Sulphacetamide Soluble Eye Drops (Sterilized)-Boots are indicated as a prophylactic in the first-aid treatment of industrial injuries to the cornea, for instillation into the eyes of new-born infants, and for the treatment of conjunctivitis and other inflammatory conditions of the eyes. Supplied in 10 and 30 per cent strengths— $\frac{1}{2}$  oz. and 1 oz. dropper bottles.

Sulphacetamide Soluble Eye Ointment-Boots is a sterile, homogeneous oculentum consisting of sodium sulphacetamide in a water-miscible base for use in conjunctivitis and other inflammatory conditions of the eye. Supplied in three strengths—2½, 6, and 10 per cent—60 gr. ophthalmic tubes.

*eight minutes to go . . .*

Doctors today find that a large number of their patients complain of constant tiredness, of 'finding everything too much', of 'feeling generally run down'. Cases of debility and lassitude caused by present-day conditions are becoming increasingly prevalent. For these conditions 'Vibelan' is of particular value. It counteracts B vitamin deficiencies, containing as it does the principal members of the B group in the balanced proportions which are necessary for effective utilisation of proteins, fats and,

more especially, carbohydrates. Each tablet contains vitamin B<sub>1</sub> 0.5 mg, riboflavin 0.75 mg and nicotinamide 7.5 mg, in a yeast extract base. Four tablets provide the normal daily requirement of these vitamins. 'Vibelan' is available in bottles of 50 tablets. Further details are available on request.

## IRRESPECTIVE OF LATITUDE

Tubes of 25 bottles of 100 and 1000 × 5 mg tablets  
Boxes of 12 and 100 × 1 cc ampoules and 10 cc  
vials of 15 mg/cc  
Folvite registered trade mark.

In many parts of the world clinicians are confirming the success of 'FOLVITE' (Folic Acid, Lederle) as a potent haematonic in macrocytic anaemias. Small oral doses of 'FOLVITE' produce a marked improvement in the blood picture and clinical condition within a few days in pernicious anaemia, sprue, nutritional and gestational macrocytic anaemias.

The Lederle Laboratories, who originally isolated and synthesised folic acid, offer the profession the experience of their medical staff.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Low Back Strain

**Q**—What is the pathology of low back strain?

**A**—The two expressions "lumbago" and "low back strain" are often used synonymously by the clinician. Low back strain implies that a strain or sprain of the muscles, ligaments, or joints of the lumbo-sacral region has occurred. The strain may be due to (1) a single injury or repeated minor traumata, (2) mechanical defects and insufficiencies, which make this part of the spine less capable of standing up to normal activities—e.g., congenital anatomical abnormalities (spondylolysis, spondylolisthesis, sacralization of the transverse processes of the fifth lumbar vertebra), and (3) structural changes following such varied conditions as fractures, scoliosis, protrusion of intervertebral disk, or osteoarthritis. The term is thus used to describe a large group of conditions of a mechanical and structural nature involving (a) muscles (sacrospinalis and gluteal muscles and their covering fasciae, when adhesions and contractures have followed inflammation) and ligaments (of the intervertebral and sacro-iliac joints), (b) intervertebral disk injuries, and (c) joint injuries other than b—e.g., strains and sprains of the facet articulations and sacro-iliac and lumbo-sacral joints.

It will be seen, therefore, that low back strain is a very general term describing pain in the lumbo-sacral region. It should be appreciated that there are many other causes of lumbo-sacral pain, which can briefly be covered under the headings "infective," "neoplastic," and "visceral."

### Treatment of Jaundice

**Q**—What is the modern treatment for catarrhal and infective jaundice with special emphasis on the diet? Are magnesium sulphate and a low-fat diet necessary or not?

**A**—The "modern" treatment of infective jaundice is simple in essence: it is to allow the patient to rest in bed until he has recovered. Recovery is complete and rapid in about 95% of cases, in about 0.3% acute necrosis of the liver proves rapidly fatal, and in not more than 5% the hepatitis passes into a sub-acute or chronic phase, often leaving a permanently damaged liver. There is little evidence that treatment affects the issue in mild cases. A low fat diet was once *de rigueur*. On theoretical grounds high protein and high carbohydrate intake is desirable, it seems as satisfactory, however, to follow the time-honoured precept that "a little of what you fancy does you good." Difficulties arise when prolonged anorexia and vomiting reduce consumption, in such cases the parenteral administration of fluids with hydrolysed proteins and a supplement of vitamins may be necessary. Similar measures are required in acute necrosis. Rest is all-important, precocious exertion can cause relapse, and it seems probable that alcohol may do the same. It is wise to keep the patient in bed until bilirubin has disappeared from the urine and for exercise to be greatly limited until urobilinogenuria is no longer present. No drugs are specifically indicated.

### Toxicity of Dioxane

**Q**—In my laboratory we have recently started using dioxane for the dehydration etc. of histological specimens. How great is the risk of toxicity from dioxane? How can we best avoid it and what symptoms and signs should we look for? Why is the method not more popular?

**A**—Dioxane is a poison, not only when ingested but also when inhaled. Recorded cases are few in number, but the symptoms of mild poisoning by inhalation appear to be those of "stomach trouble"—anorexia, nausea, and vomiting. Long exposure to dioxane vapour in low concentrations or short exposure to high concentrations will cause liver necrosis and

haemorrhagic necrosis of the kidneys, likely to prove fatal in about a week after the onset of severe symptoms. The dangerous effects of dioxane vapour are more likely to be produced under industrial conditions than in the laboratory. If dioxane is used in laboratory processes, however, proper precautions should be adopted, and the staff should be warned of the potential dangers. Barbe (*Guy's Hosp Rep* 1934, 84, 267) has reported five fatal cases. The chief reason why the method is not more used is that it makes the tissues very brittle, so that some (in particular thyroid) become quite intractable. The speed of the dioxane process is its greatest attraction, but this can be equalled by the acetone-xylol process, which does not make the tissues brittle. In several large laboratories the method has been abandoned for this reason.

### Acroparaesthesia

**Q**—Is there any recent development in the treatment of acroparaesthesia? I have in mind a busy housewife aged 45, whose hands are often in water. Since January she has had numbness of the hands and fingers. There is no pain, tingling, pallor, or cyanosis and no loss of sensitivity to heat and cold, pin-prick or vibration. For about a fortnight there was a similar sensation of numbness affecting other parts of the body after a bath. The reflexes are normal. Her general health is good, the heart and blood pressure are normal, digestion is good, menses are still regular and normal, and she does not get chilblains. Since May the numbness has almost cleared, leaving a curious sensation of extreme dryness, which she describes as very unpleasant when using her hands. During the warm weather this has improved, leaving only the finger tips affected.

**A**—Acroparaesthesia is a symptom, and treatment depends upon the cause; there is no particular treatment for the symptom as such. In a woman at the menopause the problem demands general and careful overhaul. While an endocrine or functional nervous condition is quite possibly responsible, care must be taken to exclude a nutritional, circulatory, or organic nervous cause, and this may not be apparent without prolonged observation. From the history, temperature would seem to be an exciting factor, and it is just possible that the symptoms are indicative of an incipient dermatitis, perhaps due to household irritants, or to allergic sensitivity to the primula or other plants.

### Pruritus Vulvae and Ani

**Q**—How would you treat severe pruritus vulvae and ani in a woman aged 56? She had the menopause at 47 and the pruritus started a year later. The anus is badly torn and fissured from scratching. Itching is unbearable during the day and disturbs sleep at night. She has many symptoms of late menopause—flushes, fatigue, depression, etc. There is a slight amount of sugar in the urine. Treatment by oestrogens has given only temporary relief. Is it dangerous to continue such treatment over a long period?

**A**—The treatment of pruritus vulvae and ani is unsatisfactory unless a cause can be found. The onset of the menopausal atrophy may well have made matters worse, even if it has not caused the trouble. The response to oestrogens is striking, but, as is to be expected, the effect passes off when treatment is discontinued. Complete investigation should be carried out in the hope of finding a cause. In the first place glycosuria, though it is not due to diabetes, cannot be dismissed. It sometimes favours the development of a fungous infection with intense pruritus. Other investigations should include examination of vaginal swabs for fungus and protozoal infections, a full blood count to exclude any form of anaemia, and a fractional test meal to exclude achlorhydria. If the latter is found the administration of hydrochloric acid regularly often has a dramatic effect. If a cause is not found, empirical treatment with large doses of vitamins A, B, and C in turn should be tried, also cod-liver oil applications to the vulva. Frequent warm baths or radiant heat seem to help sometimes, possibly by increasing the blood supply. The continued administration of oestrogens for long periods is not advisable, apart from any other possible disadvantage it will cause uterine haemorrhage. A carefully controlled course, with a gradual reduction in dose, extending over about two months might be tried.

**Cinchophen and Neocinchophen**

**Q**—How does the toxicity of neocinchophen or allied drugs compare with that of cinchophen? In my experience cinchophen causes digestive upset in a small percentage of patients and giant urticaria in a still smaller percentage. In over 20 years using cinchophen fairly freely but given only on three days a week for three weeks I have seen only two cases of giant urticaria and have had perhaps half a dozen patients complain of gastric disturbance.

**A**—Several observations have been made on the comparative toxicity of cinchophen and neocinchophen. Furth and Edel (*J Pharmacol* 1935, 53, 105) found that the daily administration of 0.2 g of cinchophen per kg to rats caused a loss of about 20% of body weight in eight days, whereas three times as much neocinchophen was required to produce the same effect. Barbour and Gilman (*J Pharmacol*, 1935 55, 400) stated that neocinchophen ('tolysin') is far less toxic to rats than cinchophen, which accords with the extreme paucity of clinical evidence of tolysin toxicity. The lower toxicity was not found to be due to a smaller absorption of neocinchophen. Davis (*Amer J med Sci*, 1932, 184, 555) concluded that the superiority of neocinchophen for general clinical use could be fairly assumed from the evidence in the literature. However, in 1941 the Council of Pharmacy and Chemistry of the American Medical Association (*J Amer med Ass* 1941, 117, 1182) stated:

There is no satisfactory evidence on which to base an estimate of the relative dangers in the use of cinchophen and neocinchophen in equally effective doses.

**Toxic Hepatitis**

**Q**—Is it possible to distinguish clinically or by any other method between the jaundice due to the administration of arsenicals in the treatment of syphilis and the jaundice due to a syringe-transmitted virus?

**A**—Both the jaundice due to arsenicals given during the treatment of syphilis and the jaundice due to a syringe-transmitted virus are forms of toxic hepatitis. There is no certain pathological or biochemical means of differentiating the two conditions, but the incubation period of jaundice due to a syringe-transmitted virus is usually from 80 to 110 days, whereas a toxic hepatitis is due to arsenic, if such a thing actually exists, might come on at any time during a course of arsenical drugs. A patient who is receiving antisyphilitic treatment may be incubating infective hepatitis, the incubation period of which is from 21 to 35 days.

**Retching and Vomiting**

**Q**—I understand that vomiting from cerebral or nervous causes occurs without retching. Is it true that vomiting without any suspicion of retching cannot occur from organic lesions of the stomach? In other words is the absence of retching a valuable sign against organic disease of the stomach in a case in which there has been erratic and variable vomiting over a period of six or more months? Can such vomiting in an adult occur from habit?

**A**—It is clear that vomiting or 'bringing up and ejecting the contents of the stomach by the mouth' (OED), depends on the integrated action of numerous muscles and is a complex act controlled by the central nervous system whether the exciting cause be some gastric irritant or increased intracranial pressure. Consequently the act of vomiting differs little whatever the cause, but the sensations accompanying the act may differ. It has been said that nausea is commonly absent in "cerebral" vomiting, though clinical experience shows that it is often present. The questioner omits to define his terms and thus his question is difficult to answer. To retch is defined by the OED as 'to hawk, to bring up phlegm, to make efforts to vomit, to throw up in vomiting'. If, as seems probable, by 'retching' is meant "making efforts to vomit," it is true that organic disease of the stomach causing vomiting is usually associated with retching, but the converse is not necessarily true. "Erratic and variable vomiting" continuing for six months without the appearance of unequivocal signs of organic disease raises a strong suspicion of hysteria, in this sense such vomiting can certainly occur from habit.

**Varicose Veins**

**Q**—All textbooks consulted give only sketchy details confined to Trendelenburg's test and contraindications for injection of varicose veins of the lower limbs. Can you describe (a) the various tests (b) what each test shows about the deep connexions and functioning of the veins and (c) the treatment indicated by each interpretation of each test?

**A**—The contraindications for injection are old age and general disease—e.g., diabetes—previous deep thrombosis, or bad history of recurring phlebitis. The various tests—Trendelenburg, Perthes, Ochsner, and Mahorner—are rather academic and not very important in deciding on the appropriate treatment. When the condition has developed beyond the stage where injection treatment is likely to be successful the usual procedure is to tie the varicose internal saphenous vein at its junction with the femoral vein and at the point where it crosses the internal malleolus, and to inject the vein while exposed in the wound with one of the sclerosing agents. For anaesthetized patients 20 ml of sodium chloride (30%) is suitable. If the external saphenous vein is at fault it is tied and injected in the popliteal space and in the sulcus behind the external malleolus. If a connexion with the deep veins seems to be persisting after this treatment, either just above or just below the knee, it would be wise to put in another ligature in the appropriate place.

**NOTES AND COMMENTS**

**Second Attack of Measles**—Dr W. L. YOUNG (Heywood, Lancs) writes: I was rather interested in the reply on the above subject ("Any Questions?" Aug 14, p 363). While I was of course aware that second attacks of measles were rare, I did not imagine that they were so uncommon as your reply seemed to suggest. In last year's epidemic I attended approximately 100 cases. This year there have been two of those who have had a second attack. In both instances the symptoms and signs were typical, and though there is this year a co-existing epidemic of rubella I see no reason to doubt my diagnosis.

**Corrections**

In the report of a meeting of the Section of Surgery at the Annual Meeting of the B.M.A. on Friday, July 2 (*Journal* July 17, p 155), some of the figures quoted by Lieut Col W. L. Harnett (London) were wrongly recorded. In the first paragraph "only 53 patients" should read "only 83 patients". The first sentence of the second paragraph should read, "When the cases were subgrouped into stages there was a five year survival rate of 68.2% in Stage I, 43.6% in Stage II, 25.6% (not 59%) in Stage III with lymph node involvement, and 59% (not 25.6%) without it". The last sentence in the second paragraph should read, "One hundred and seventy five patients were treated by radium, with or without surgery, and 26.5% (not 63.4%) of these survived five years".

In the annotation "The Reflecting Microscope" which appeared in the *Journal* of Aug 7 (p 306) we referred to the work of "Dr R. Brer, of the Department of Anatomy and Physiology at Oxford". There are of course separate Departments of Anatomy and Physiology at Oxford, and Dr Brer works in the Department of Human Anatomy.

In the leading article on "Streptomycin in Use" in the *Journal* of Aug 21 (p 391) we erred in stating that the M.R.C.'s Committee on Streptomycin decided 'to restrict the use of the drug to cases of tuberculous meningitis and military tuberculosis'. This should have read, 'The Committee decided to restrict tests at the outset to a few acute and usually fatal forms of the disease, including tuberculous meningitis in children and acute military tuberculosis'. The M.R.C.'s Streptomycin in Tuberculosis Trials Committee has since 1947 made a controlled investigation of the effects of streptomycin in pulmonary tuberculosis and it is hoped to publish the results of this work in the *British Medical Journal* this autumn.

LONDON SATURDAY AUGUST 28 1948

## LASSITUDE, COLDNESS, AND HAIR CHANGES FOLLOWING PREGNANCY, AND THEIR RESPONSE TO TREATMENT WITH THYROID EXTRACT\*

BY

H E W ROBERTON, MA, MD

It is common in Christchurch, New Zealand, to find mothers of young babies in a poor state of health and suffering from fatigue out of all proportion to the work they do. In almost every case there are also intense irritability, undue coldness, and dryness of the hair, usually with a tendency to abnormal loss of hair. Treatment with thyroid extract gives dramatic relief. Myxoedema, gain in weight, cracked voice, and loss of eyebrows are not found, but other symptoms of mild hypothyroidism (Warfield, 1930, Werner, 1942) are found in varying degrees. The usual descriptions apply to cases of hypothyroidism of menopausal age rather than the third decade. Young nulliparae have symptoms which appear to be identical with those found after pregnancy (Robertson, 1946).

On questioning 219 unselected patients with 483 pregnancies it was found that many had mild symptoms. In 114 cases the therapeutic test with thyroid extract confirmed the diagnosis.

For all pregnancies recorded the incidence was as follows. No symptoms of hypothyroidism, 225 (53%), doubtful symptoms, 54 (11%), mild symptoms, 127 (26%), severe symptoms, 47 (10%). Where the last pregnancy only is considered there were 13% with severe symptoms and 33% with mild symptoms.

### Case Histories

**Case 1**—A patient aged 22 had slight enlargement of the thyroid. She felt well after the first pregnancy. She was good-natured, always smiling, and justly proud of a fresh complexion and long silky fair hair. A year after the birth of the second baby she came "for a tonic," complaining of having been tired and nervy for the last 9 months. Her complexion was dull and muddy. Her hair was coarse, her clothing, which was unduly thick for warm weather, was untidy, and she had no smile. She confessed to being so irritable with her husband that it was a wonder he put up with her.

After 2 weeks' treatment with thyroid extract, 1 gr (65 mg) daily for 2 weeks and then  $\frac{1}{2}$  gr daily for 4 weeks, she regained her normal health and appearance. After this she stopped treatment and relapsed. During the 6 months of relapse she had not the energy to come for further prescriptions, and by the end of that time she was not on speaking terms with her husband. She then took thyroid regularly for 5 months, after which she was able to leave it off with out further relapse.

**Case 2**—This case was found on routine questioning after the second pregnancy. The patient, aged 36, said that she had felt well after the first pregnancy. When the second baby was 3 months old she began to feel tired and attributed this to the amount of work she had to do. She did not complain of the cold, but her husband reminded her that it was the first time that she had used a hot-water bottle all through the summer. She said that her hair was dry and lifeless, and had a tendency to come out. Normally placid, she complained of 'nerves,' and her husband, who had previously looked on her as the best-natured woman he had ever met, complained of her temper.

She returned to normal on  $\frac{1}{2}$  gr of thyroid six daily.

\*An abridged version of the paper awarded the Sir Charles Hastings Clinical Prize.

### Signs and Symptoms

The patients complain of being more tired than they should be in relation to the amount of work they are doing. They have to drive themselves, and become extremely irritable and depressed from fatigue. They are disappointed at being unable to enjoy looking after the baby, bewildered by their failure, and afraid of a future unhappy married life. They admit treating their husbands and children badly, and are afraid of losing their affection; they are also conscious of loss of looks. As a rule they go to sleep easily but have restless nights. Nightmares are a constant symptom. They always complain of feeling the cold more than previously. There is also intolerance of heat, which is apt to cause confusion in diagnosis.

Loss of hair from the head, but not from the body, is found in the more severe cases, the hair coming out at the roots. In all cases the hair becomes dry and straight and loses its lustre. This is due to lack of oil in the hair, and clears up within several weeks of beginning treatment. The pulse is normal or rapid, never unduly slow. Palpitations and effort syndrome are common. The skin of the face becomes greasy, with a tendency to acne, and a muddy tinge. The face has a slightly bloated appearance, and there is rarely slight puffiness of the ankles, but otherwise no oedema is found. Loss of weight up to a stone (6.3 kg) or two is usual in the more severe cases; gain is extremely rare. Dysmenorrhoea, sterility, and abortion are relatively common, and there is frequently enlargement of the thyroid at the time of the menses.

The basal metabolic rate is in the lower normal zone. In 22 cases there was variation from -32% to +20%, and 16 of these were in the zone -10% to +10%. Some of the patients were too nervous to attain a truly basal state as out-patients. The basal metabolic rate is unsatisfactory and even misleading in the diagnosis of the milder cases of hypothyroidism.

Symptoms may appear at any time from 1 to 12 months after parturition, usually within the first 4 months. Untreated patients may recover spontaneously any time after 9 months from parturition, or may not recover for some years. If there is a further pregnancy while the symptoms are still active those who show the "warmth of pregnancy" lose them at 4-5 months. The remainder, fortunately a minority, have increased severity of symptoms, or, if taking thyroid, require an increased dose. There is almost always a relapse after a subsequent pregnancy, and there is a tendency for the condition to become more severe after each successive pregnancy. Often symptoms do not appear until after the second or third.

### Treatment

Symptoms improve considerably or disappear on 1-4 gr (65-250 mg) daily of active dried thyroid extract. Improvement is definite within 3-4 weeks.

Thyroid extract provides substitution therapy while spontaneous cure takes place, and also appears to hasten spontaneous cure very considerably. Most patients can stop treatment without relapse after 4-6 months, but in others symptoms reappear within 2 months of stopping treatment.

### Relation to Goitre

Goitre is endemic in Christchurch. In this series the thyroid gland was invisible in 18% of the patients, visible on careful examination in 47%, obvious in 31%. The remaining 4% had suffered thyroidectomy.

The relationship of goitre to the severity of symptoms following pregnancy is shown in the following table

	Severity of Symptoms Following Last Pregnancy			
	Nil	Doubtful	Mild	Severe
Thyroid invisible	18 (47%)	5 (13%)	13 (34%)	2 (6%)
" small	43 (42%)	12 (12%)	32 (31%)	15 (15%)
" obvious	27 (40%)	9 (13%)	21 (31%)	11 (16%)
Thyroidectomy	0	0	3 (38%)	5 (62%)

There is a statistically significant difference ( $p < 0.01$ ) between the "invisible" and each of the two "visible" groups

Thyroidectomy almost always leads to hypothyroidism following pregnancy. Further cases of pregnancy following thyroidectomy collected since this table was prepared bring the number to 15. Of these only 2 failed to show symptoms after the first pregnancy. One of these developed severe symptoms after the second, the other has not become pregnant again.

Symptoms after pregnancy occur more frequently in patients who have shown active enlargement of the thyroid during pregnancy.

Body warmth is decreased in hypothyroidism, but the converse, that coldness is due to thyroid deficiency, does not hold. According to my observations thyroid extract in non-toxic doses is ineffective for chilblains in the absence of dry hair and lassitude. Women who are sensitive to cold before pregnancy have an increased tendency to hypothyroidism following pregnancy, as seen in the following table. The difference can be accounted for by a number of cases of already existing hypothyroidism.

	Symptoms Following Pregnancy			
	Nil	Doubtful	Mild	Severe
Normally warm	52 (51%)	15 (15%)	25 (25%)	9 (9%)
" cold	41 (36%)	12 (10%)	44 (38%)	18 (16%)

The difference is statistically significant ( $p < 0.01$ )

The average duration of lactation in cases showing symptoms of hypothyroidism is 3.9 months, in those without symptoms 4.1 months. The difference can be accounted for by unnatural weaning because the mother is tired. Weaning brings about no improvement in the symptoms.

### Discussion

The syndrome of lassitude, coldness, and hair changes following pregnancy has not been described previously. It appears to be a condition of very mild hypothyroidism. The normal basal metabolic rate readings raise some doubt about the hypothyroidism. They are, in fact, slightly lower as a group than the rates of others undergoing routine examination in Christchurch. Mazer and Goldstein (1932), Werner (1942), and Shelton (1941) mention the frequent occurrence of hypothyroidism in individual cases without a low B.M.R.

I have shown that there is an association with goitre, and a stronger one with thyroidectomy. The therapeutic test appears to confirm hypothyroidism. The remarkable finding is that the association with goitre is not more obvious, and that it needs statistical analysis to confirm it. In a group of women in which only 18% have no evidence of thyroid enlargement it is likely that there is some abnormality even in this 18%. It is also likely that many of the other 82% have a successful hyperplasia, providing a sufficient reserve of active tissue. Even after thyroidectomy there can be sufficient to allow the normal warmth of pregnancy.

There is a striking resemblance between these cases and Sheehan's cases of Simmonds's disease following post-partum necrosis of the anterior pituitary with mainly thyroid symptoms (Sheehan, 1939). However, in Sheehan's cases there was no lactation, there is a history of post-partum haemorrhage, and the symptoms are more or less permanent except that they are completely relieved by further pregnancy.

Until further evidence is forthcoming I would suggest that the most satisfactory explanation of the condition is that (1) the thyroid gland is defective to the extent of requiring strong pituitary stimulation, (2) the latter is given during pregnancy,

and withheld after pregnancy until the menstrual cycle is again established normally. In the more severe cases a vicious circle is set up, and a general endocrine disturbance remains which can be rectified with thyroid extract. Chapman and Higgins (1944) showed that thyroidectomy and iodine deficiency together affect the pituitary, so it is possible that iodine deficiency is another factor.

The almost certain occurrence after thyroidectomy is a very strong argument against promiscuous thyroidectomy in all cases of goitre, which, though nearly extinct in this part of the world, still has its advocates. The 15 cases of thyroidectomy quoted by no means all followed toxic goitre. At least two were suffering from hypothyroidism, mistaken for hyperthyroidism, at the time of the operation.

### Differential Diagnosis

Attempts at objective measures such as elasticity of the hair, thermopile measurements of skin temperatures, metabolic rates and so on are unsatisfactory. The therapeutic test was reliable when English-made thyroid extract was available, but less so now that it is necessary to use Australian extract. Even with the least unreliable brand it is often necessary to give two months' trial and larger dosage.

The most common error in diagnosis is that of mistaking the condition for toxic goitre. The patient with hyperthyroidism complains of 'nerves,' loss of weight, tachycardia, and, if questioned, intolerance of heat. There is tremor of the fingers and an enlarged thyroid gland. A low metabolic rate, it is said, does not altogether exclude toxic goitre, and in any case the failure of a nervous woman to relax and achieve basal conditions may easily give a false high reading. More careful questioning should disclose hair changes and sensitivity to cold.

The condition is easily mistaken at first sight for pulmonary tuberculosis, and when it fails to respond to thyroid extract it is necessary to exclude coexisting tuberculosis. The reliable symptoms are lassitude, coldness, and hair changes. In the absence of one of these thyroid extract is unlikely to give relief, while in the presence of all three it is almost certain to do so.

Though the condition as seen here is associated with endemic goitre, I have histories of two patients who developed it before leaving England. It is probable that, if looked for, it would be found in goitre-free countries in women who have undergone thyroidectomy and in families with a history of goitre.

### Summary

The syndrome of lassitude, coldness, and hair changes after pregnancy is associated with endemic goitre, and is usual when pregnancy follows thyroidectomy. It responds to treatment with thyroid extract.

### PERMANENT APPOINTMENTS IN R A F

The Royal Air Force is short of officers on the permanent staff of the Medical and Dental Branches. Doctors and dentists who have left the Royal Air Force on release and who are interested in making a career in the Service are invited to apply for permanent appointments in the Medical and Dental Branches. Appointments will be made by interview, and selection will of course be subject to suitability of candidates. Applications should be addressed to the Air Ministry (MA 1) Awdry House, Kingsway, London, WC 2. All suitable officers now serving on short service commissions are being considered for permanencies, and permanent commissions are being offered also to doctors and dentists who served in those branches during the war and who have now returned to civilian life.

## NATIONAL INSURANCE

### POSITION OF MEDICAL AND DENTAL PRACTITIONERS

*A number of doctors have been in doubt whether they should class themselves as employed or self-employed persons when completing the National Health Insurance Form CF6. The Ministry of National Insurance has recently issued the following statement for the information of doctors and dentists*

The National Insurance scheme applies, with minor exceptions, to all persons in Great Britain who are over school-leaving age and under pension age. Insured persons are divided into three classes. Class 1, employed persons, Class 2, self-employed persons, and Class 3, non-employed persons. Employed persons are those who are gainfully employed under a contract of service. Self-employed persons are those who are otherwise gainfully occupied. Non-employed persons are those who do not fall into either of the other two classes. Employed persons are also insured under the Industrial Injuries scheme.

A medical or dental practitioner engaged in the ordinary professional work of attending patients is not normally employed under a contract of service and would therefore fall into Class 2 as a self-employed person. In order to establish that a practitioner who is thus engaged is employed under a contract of service it would be necessary to show that he was subject to direction and control in matters of detail as to the method of performance of his work. The relationship between a patient and his doctor or dentist is not of this character, and accordingly practitioners engaged only in private practice should regard themselves as self-employed persons—i.e., in Class 2. Similarly doctors and dentists on the lists of executive councils under the National Health Service will be insurable as self-employed persons in respect of their work in that capacity. The weekly contribution of self-employed persons is 6s 2d for a man and 5s 1d for a woman.

The National Insurance Act, however, enables statutory regulations to be made modifying the classification of insured persons where the circumstances or nature of an employment render it desirable. The effect of the regulations which have been made, as far as practitioners are concerned, is as follows.

Doctors or dentists who are engaged full time in a hospital or mental institution or a maternity or convalescent home (including any associated clinic or dispensary or out-patients department) are insurable as employed persons in Class 1 and also under the Industrial Injuries Scheme. The position is the same where the engagement is not for whole-time services but the duties normally occupy more than half the practitioner's time and he is paid on a salary basis.

Doctors or dentists, on whatever basis they are paid, who are engaged full time in employment under a public or local authority (e.g., as medical officers of health or assistant medical officers of health or in the school medical or dental services) are insurable in Class 1 as employed persons and under the Industrial Injuries Scheme. This also applies to the practitioner who works for more than one such authority if the duties in the aggregate occupy full time, and to the practitioner whose engagement is not for whole-time services but whose duties for the authority occupy more than half his time provided that he is paid on a salary basis.

Similarly doctors or dentists engaged by commercial firms or business organizations who are rewarded for their services by salary and who spend the whole or more than half their time on their duties for any one such employer are treated as employed persons under both schemes. An assistant or locum paid on a salary basis for duties occupying the whole or more than half his time is also insurable as an employed person.

The total combined national insurance and industrial injuries contribution for an employed person is 9s 1d a week for a man and 7s 1d for a woman of which the employee's share is respectively 4s 11d and 3s 10d.

Mr C E A Bedwell has been appointed, on the nomination of the Camberwell Hospitals Management Committee, by the South-East Metropolitan Regional Hospital Board to succeed the late Mr Harold Gibbons as chairman of the committee.

## PROCEDURE FOR CLAIMING COMPENSATION IN SCOTLAND

The Secretary of State for Scotland has announced that executive councils in Scotland will notify doctors taking part in the National Health Service of the procedure to be adopted in claiming compensation for loss of right to sell the goodwill of their practices. A sum of £66 millions is available for distribution to doctors in Great Britain to meet such claims. Oct 31, 1948, has been fixed as the last day for submitting claims, and only in special circumstances will a claim sent after that date, but before April 30, 1949, be admitted. It is important that claims should be made promptly, since it will not be possible to allocate the total amount of compensation available until a decision has been reached on all the claims submitted.

Under the National Health Service (Medical Practices Compensation) (Scotland) Regulations, 1948, compensation will normally be payable to doctors engaged as principals in general medical practice immediately before July 5, 1948, and whose names on that date were entered on the medical list of an executive council as practitioners undertaking to provide general medical services or maternity medical services under the new Health Act. Those doctors in the Highlands and Islands Service whose practices have not been bought and sold in the past are not affected.

Compensation will also be payable to doctors, or the personal representatives of doctors, who died or retired between Nov 5, 1946, and July 5, 1948, so long as no part of the goodwill of their practices has been sold. In general, each practice will be allocated a share of the total sum in proportion to the average gross yearly receipts of the last two accounting years before July 5. In the case of partnerships, the regulations leave the sharing of the practice compensation to be determined after a legal committee now considering this question have reported.

## INTERNATIONAL HOLIDAY EXCHANGES

In view of the growing number of inquiries regarding holiday exchanges that have been received from doctors in this country and on the Continent, the BMA proposed to the World Medical Association that active steps be taken to encourage the development of such international contacts. The suggestion was readily accepted by the WMA and each national medical association has now been invited to maintain a register of members who are prepared to offer hospitality for a holiday period. The names of members who would like to take part in the scheme will be submitted to the appropriate national associations.

The scheme is divided into two parts, the first being applicable to doctors and their wives and the second to the children of doctors who are old enough to appreciate and gain benefit from a holiday abroad.

During the past season the BMA has put several members in touch with doctors on the Continent and it is expected that interest in the exchanges will grow in the future. An appreciable interval may sometimes elapse before a suitable exchange can be effected and the Association is therefore anxious to lose no time in registering the names of doctors who might like to take part during the summer of 1949. Members wishing to make an exchange, either for themselves or for their children, are invited to communicate with the Secretary, giving relevant details. The Association cannot, of course, give any recommendation about the suitability of addresses obtained under this scheme, and the final decision to make an exchange must obviously rest with the doctors concerned.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar  
*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley

## Correspondence

### Compensation for Loss of Goodwill

SIR—I was interested in Dr T T Hardy's letter in regard to this subject (Aug 14, p 87), and think that it would only be just if ex-Service practitioners were allowed to claim as their basis of compensation the average of the last three financial years before their period of service plus a betterment factor.

As in Dr Hardy's case, I returned to a single-handed private practice, which had to be rebuilt from the ground. The loss of income during the war years and the need for building up one's practice were accepted as a war sacrifice. However, if we are to receive also a reduced sum in compensation as a result, in addition to our accepted loss, it will leave a very great feeling of dissatisfaction among ex-Service doctors. Nor will it help in the recruitment of young medical officers into the reconstituted Territorial Army if they feel their interests are likely to be ignored in a similar way.

The note from the Secretary of the B.M.A. is not a sufficient explanation. Our case should not be judged by a committee, like claimants for outdoor relief. It should be granted to us as a right that the basis of our compensation should be taken as the average of the three financial years just before service plus a betterment factor. This was thought to be the basis throughout the time of discussions.

If this anomaly is not corrected, then we ex-Service general practitioners will feel that our negotiators have let us down. I feel that if both the Minister of Health and the Minister for War were aware of the facts the necessary amendments to the regulations would speedily be made—I am, etc.,

Newcastle upon Tyne 2

H B PORTEOUS

\*\* A statement by the Ministry of Health on this subject was published in the *Supplement* last week (p 89)—ED B.M.J.

### Pharmaceutical Services for All

SIR—Here is a problem. Mrs A does not wish to leave Dr B, who has attended her for very many years. Dr B does not wish to join the N.H.S., but prefers to retain his freedom. Under the Act Mrs A is still entitled to hospital services, but as Dr B has not the N.H.S. prescription forms she is unable to obtain the chemist's services for which she is taxed. Again, the old retired practitioner who can still prescribe for his wife is also denied the prescription forms for his own use. The only remedy for these difficulties is for the prescription forms to be available to all registered practitioners.

Perhaps these, together with all the other important details of administration, will be borne in mind by the Negotiating Committee—I am, etc.,

London NW 3

LEWIS G GLOVER

### Reflections on Superannuation

SIR—I was interested to read the remarks of the Secretary of the British Medical Association in reply to my letter (Aug 7, p 79). I appreciate that the difference between the percentage rates of superannuation between general practitioners and local government medical officers is somewhat counteracted by the differing periods of remuneration on which the percentage is calculated, but I still consider that the general practitioner has been treated favourably as compared with the majority of local government medical officers, my view being largely based upon certain conclusions to which I have come after a close examination of the tables provided in the Spens Report.

By a close analysis of the tables in the Report it appears that on 1939 incomes (augmented as suggested on p 12 of the Report) the average annual income during 40 years' G.P. service over that whole section of the profession was £1,232. In 40 years' contributory service, therefore, the total income of the average practitioner would have been £49,305 giving an average pension of £740. This may be compared with (1) the minimum pension of £770 receivable by a medical officer of health of a county council (population 600,000), or (2) a pension of £750 receivable by a deputy medical officer of health of a county borough (population 800,000), if that deputy had been paid 25% above the minimum scale for the last three years of his service.

But while these comparisons appear reasonable they are quite fallacious, how can one possibly compare the average pension payable to a general practitioner with the pension payable to the highest grades of medical officers of health? There are many qualified whole-time workers in the public health service who are not, nor cannot expect to become, medical officers of health of authorities as large as those quoted above, nor is the average medical officer of health, I imagine, receiving 25% above the minimum scale when he retires. It is for this reason that I still hold that the average general practitioner has received more favourable consideration than the average local government medical officer in respect of retiring pensions—I am, etc.,

Worthing Sussex

HAROLD LEESON

### Independence of Medicine

SIR—I have read the spate of dissatisfied letters in the *British Medical Journal* this week with interest. They are coming in even earlier than I expected. I can only urge the writers, and all others who come under the "lower than vermin" category, to signify their approval of Lord Horder's proposed organization. This is an organization to maintain the independence of Medicine. I will gladly post the necessary forms off to anyone interested. Lord Horder never wavered, like some of the ditherers on our Council, but was consistent throughout the controversy. His opinion of the Minister of Health and his purposes which should have been patent to anyone, is now being proved only too true a forecast—I am, etc.,

Hampstead

H V DEARIN

### Recruitment of Young Practitioners

SIR—I am at an entire loss to understand how the recent action of the Minister of Health, taken on the advice of the Medical Priority Committee, can have been so complacently accepted by the profession—with but one protest from Dr Nicolas Malleon (*Supplement* July 3, p 27). Surely there are still some other doctors who remember the value of their house appointments? Even during the war the Service medical departments insisted on a minimum of six months' postgraduate experience, which, with few exceptions meant tenure of an "A" post and this was clearly regarded as the very minimum amount of postgraduate experience acceptable for a doctor in independent practice. At the end of an "A" post the young practitioner is beginning to acquire confidence in himself and in his own decisions, and a further six months in a "B2" post, at least, is essential as was recognized by the Goodenough Committee, to consolidate that confidence and to fit him for the responsibility of making decisions which cannot be rapidly "vetted" by his seniors, which he must be able to do as soon as he leaves the sheltered environment of a hospital, even in the Services. That extra six months does far more than double his postgraduate experience, and yet because of an arbitrary decision all those students who were unfortunate enough to qualify at the end of 1947 or beginning of 1948 are not to be allowed to take a "B2" post, and if they are so unfortunate as to be nearly 26 they are not even to be allowed to take an "A" post.

In his Parliamentary answer to Sir Ernest Graham Little reported in your issue of July 3 (p 55), the Minister said that he was fully aware of the implications of this decision. If this is so, it means that the implications have been explained to him by his professional advisers, yet surely such a decision could not have been taken in peacetime if his advisers had really given him an accurate picture of the value of the first year of postgraduate experience.

How has this shortage suddenly arisen? No reason is given yet there can have been no sudden decrease in the numbers of doctors qualifying—certainly a proportion of them will be ex-Servicemen not subject to further compulsory service, but the needs of the Services must also be diminishing. Why cannot at least a reasonable and factual explanation have been given for this decision? There will be no point in suggesting that further postgraduate experience can be obtained by these doctors when they have left the Services, because any recently demobilized doctor can tell how difficult it is to get a resident hospital appointment, even if he can afford to do so. Moreover there is no mention of any special compensatory arrangements which might have been made in order to make it easier for this group to get further experience on demobilization.

The present arrangements are to be reviewed towards the end of the year, and then, if there is no protest from the profession, and the demands of the Services remain the same and the scheme has proved administratively convenient, it may be retained. If, however, this "temporary" scheme is abolished, what will have been gained? One "six months' quota" of doctors will have been added to the Services, and will have had their whole future careers prejudiced, so important is the immediate postgraduate period.

Surely a more reasonable compromise could have been reached by altering the demands of the Services—e.g., as regards medical standards and the greater employment of women, as suggested by Dr Malleson—and, as this is "an expected deficiency," by stretching out the demobilization programme. A few months' extra service at the end of two years or more would certainly do less harm to a career than the missing of an opportunity of a "B2" post. I would certainly do an extra six months service in order to enable another doctor to take a "B2" post as I was able to do myself, and I feel sure that many others feel the same—I am, etc.,

SURGEON LIEUTENANT -

### Rural Practice

SIR—With reference to Dr T. Smallhorn's letter (Aug. 7, p. 78), the only machinery in the new NHS for levelling out the difference in remuneration between urban and rural practices is the mileage fund. In making final arrangements for the distribution of this fund the Minister of Health should be made to understand clearly that this fund will have to cover more than merely the cost of running a car. It must certainly include an allowance for telephone expenses and an adjustment of the time-distance factor.

As Dr Smallhorn points out, the rural practitioner may have to work very much harder with 3,000 patients on his list than the town doctor with 4,000. If the adjustments covered by the mileage fund are not sufficient, the remuneration, and later the pension, of the rural practitioner will be lower than that of the town doctor, and in consequence the standard of rural practice will deteriorate. It is of greatest importance to the new service that there should not be an actual or an apparent inferiority in being a rural practitioner.

The negotiators should see to it that the mileage fund is adequate to meet these added requirements. Also the unit value of the greater distances—say over 3-4 miles—should be stepped up. This would help to adjust the time-distance factor—I am, etc.,

Metheringham, Lincoln

### Certification under the Health Service

SIR—I was hoping that under the new Health Service there would be an end to much ridiculous and unnecessary certification, especially as the Government appointed a committee by a surprising coincidence presided over by an old school-fellow of mine, to investigate the question.

Very frequently I have patients who come to me with fractures of arms or legs. I send them, with a note to hospital, where the casualty officer takes on the responsibility of their treatment, and more often or not the resident responsible does not communicate with me. The injured limb is encased in plaster-of-Paris and after attending the hospital two or three times—probably by ambulance, for which I am required by the patient to give a certificate each time he goes—he is told to come again in three or four weeks. During this period he usually expects a weekly certificate. On these certificates I am asked to state that I have examined the patient on the day of issuing the certificate. The patient may live several miles from the bus route. Visiting him may entail a journey for me of anything up to sixteen miles. Obviously if his limb is encased in plaster-of-Paris it is impossible for me "to examine" him in any ordinary meaning of the word, unless I remove the plaster case, which would be unnecessary and detrimental to his condition. It is also obviously unnecessary that I should examine him or issue certificates at such short intervals. When a man has a fracture or an abdominal operation it should be possible to issue certificates from the beginning at much longer intervals.

Some years ago I used to attend a man living in an isolated cottage at the top of a hill. Visiting him involved a journey of some miles and climbing up a very steep and often slippery path. The only reason he was incapable of work was that one of his lower limbs had been amputated. For many years I was required to visit him (at monthly intervals) in order to be able to state that I had examined him, and that he was still incapable of work, but as far as I could judge there was no likelihood of his lower limb growing again.

At one time, about fifteen years ago, in order to comply with the certification regulations, I was regularly visiting (at monthly intervals) some twelve to fifteen chronic patients whose physical condition was stable and did not require any treatment. Apparently the absurdities under the old N.H.I. Act are being perpetuated in the new Health Service.

On the new certificate book there is printed "The date of fitness to resume work must not be later than the third day after the date of the certificate. In any other case the doctor should see the insured person again before giving a Final Certificate." Why? In many cases this involves a totally unnecessary piece of work for the doctor and perhaps an unnecessary waste of time and expenditure on fares for the patient.

Still a further rule, wasting doctors' and patients' time with no benefit to either, is the necessity for making out a fresh prescription for every bottle of medicine. Probably more people come because of coughs than for any other complaint. Most people seem to manage to consume a pint of medicine before they recover from their cough. Some require rather more, some considerably less. If I prescribe, say, an 8-oz (227-ml) bottle the patient probably attends three times at my surgery. If I give pint bottles probably a great deal of medicine is wasted.

If we could stamp our prescriptions "To be repeated not more than three times" much time and medicine would be saved—I am, etc.,

Rainham Kent

W. U. DESMOND LONGFORD

### The Young Specialist

SIR—May I, as one involved in the matter, be permitted to sketch the purely practical history of a specialist as visualized by the Spens Report? He qualifies at the age of 25 (due to conscription). He then takes his first house job. What is his salary? The Spens Report does not even admit his existence and commences with the man already one year qualified (Grade 3). Presumably our embryo specialist will continue to receive £120 per annum "plus full residential emoluments."

At 26 years old his existence is recognized, *mirabile dictu*. He achieves Grade 3—salary £600 per annum non-resident. Two points now arise. (1) Is there such a job, and, if there is, how many? (2) If he continues as a resident, presumably he will lose £200 per annum for the "full residential emoluments." The lucky man is earning about £400—not much more than he earned in "the wicked past."

At 27 years old his salary is £700 per annum (Grade 2), less emoluments, leaving £500 less tax. What if our hero was sufficiently foolish as to have married and to have the temerity to want to start a family?

At 29 years old his salary is £900 per annum (Grade 1) gross. Presumably by now, somewhere in his life cycle, he has obtained a higher degree and has incurred the attendant expense of fees for the examination and special courses, and possibly unpaid time off for study. There is usually no financial aid. If he achieves this at 28, he is one year under the "allowed age." The Spens Report suggests 29 years as the youngest for Grade 1 status. This brings us then to the implication that age is the important factor. How like the Colonial Medical Service and the Army, and how wrong!

Let us compare our intrepid hero, who is now a "specialist" at 28-29 years of age and earning £900 per annum, with the man who entered general practice aged 26 years. By the Minister's own contention he should be earning £1,300 per annum at least. I am not concerned with the increased cost of living that is mentioned in the preamble of the Spens Report. We are all in the same boat here.

These sordid facts admittedly ignore the consolations of unlimited zeal. But they are worth discussing precisely because

the Spens Report was put forward as a practical remedy for a problem it clearly inferred—viz, that it is at present a practical impossibility to achieve consultant status without private means on merit alone. Gladly conceding that the Report represents some improvement on the present impasse in the matter, one can hardly describe it as an inviting proposition to "Ability without Means," even assuming an ideal system of appointments on merit.

No matter how much we love our work—and even the loudest grumbler would not change—there is no excuse for taking advantage of our moral senses and obligations. After all, doctoring is our method of providing for our families—I am, etc.,

London W 8

JOHN Z GARSON

### Free Bottles

SIR—Under the National Health Scheme bottles and containers are supplied free. The chemist is paid 2½d a bottle. Suppose the average number of bottles prescribed per doctor per day for six days a week is twenty, and if 30,000 doctors join the Service, then the annual cost is £1,950,000. The weekly reward to a doctor for his services per patient is only slightly more than the cost of an empty medicine bottle. Perhaps later on kind Mr Bevan might award us an addition to our pay equal to the cost of one more empty bottle a week?—I am, etc.,

Brasted Kent.

T A WESTON

### Remuneration of G P s for Hospital Work

SIR—Good luck to the Haywards Heath doctors, whose letter appeared in the *Supplement* of Aug 14 (p 84). Let them stress not the time factor merely but the quality of their work. Let them point out that the skill needed in the cottage hospitals of England, which cater for the minor maladies of our people, may be as great as that which emanates from Harley Street and often more useful. But the central problem of the moment is how to discover, encourage, and suitably reward this most exacting work of our profession—I am, etc.,

Buxted Sussex

W R E HARRISON

### SUPPLEMENTARY AND STANDARD PETROL

Most members already receive supplementary petrol allowances, but it is important that they should apply for the standard ration, which was reintroduced on June 1, since it will be deducted from their supplementary allocation in the next rationing period. To enable motorists in this position to save sufficient coupons from the current standard ration book to be used after Nov 30 in place of the deducted portion of the supplementary allowance, standard coupons will be valid for the following periods:

Coupons marked	Valid for use between
First month	June 1, 1948, and Nov 30, 1948
Second month	June 1, 1948, and Dec 31, 1948
Third month	June 1, 1948, and Jan 31, 1949
Fourth month	June 1, 1948, and Feb 28, 1949
Fifth month	June 1, 1948, and March 31, 1949
Sixth month	June 1, 1948, and April 30, 1949

From Dec 1 onwards no deduction for the standard ration will be made in arrears, and the following table shows the method to be followed by regional petroleum officers in the interim period in adjusting supplementary allocations. For the purpose of illustration it is assumed that the supplementary allocation is 6 gallons per month—i.e., 36 gallons for the 6 monthly rationing period. The effect of deductions for different periods of validity is indicated, the standard ration being taken as 3 gallons per month.

Start of Rationing Period	Previous Supplementary Allowance	Deduction for Standard		Supplementary Issue	Standard Ration Issued	Petrol Issued for the Current Period	From Previous Standard	Total Petrol Available
		In Arrear	In Advance					
Aug 1	36	6	18	12	18	30	+ 6	36
Sept 1	36	9	18	9	18	27	+ 9	36
Oct 1	36	12	18	6	18	24	+ 12	36
Nov 1	36	15	18	3	18	21	+ 15	36
Dec 1	36	Nil	18	18	18	36	+ Nil	36

## H M. Forces Appointments

### ROYAL ARMY MEDICAL CORPS

Majors E Bennett and S G Walker, retired and re employed, late R A M C, have been restored to the ranks of Lieutenant Colonel and Colonel, respectively, on ceasing to be re employed.

Major G M Robertshaw has retired receiving a gratuity and has been granted the honorary rank of Lieutenant Colonel.

Captain (War Substantive Major) H O P McSheehy, M C, to be Major.

*Short Service Commissions*—Captain L H Pimm has retired on account of disability and has been granted the honorary rank of Captain. Captain D E Marmion, from T A, to be Captain. Captain W L Sanders from Emergency Commission to be Captain. Lieutenant A H B Rydon, from Emergency Commission, to be Lieutenant.

### REGULAR ARMY RESERVE OF OFFICERS

#### ROYAL ARMY MEDICAL CORPS

Majors C H G Penny and C J H Sharp, M C, having exceeded the age limit of liability to recall, have ceased to belong to the Reserve of Officers.

### TERRITORIAL ARMY

#### ROYAL ARMY MEDICAL CORPS

Captain (War Substantive Major) J M Lees to be Major.

Captain K C Hutchin to be Major.

Captain W J Atkinson to be acting Major.

Lieutenant G E Parker, D S O, to be Captain, and has been granted the acting rank of Lieutenant-Colonel.

Lieutenants G L Broderick, J H Orr, and J R McBoyle to be Captains.

R T G Craig to be Lieutenant.

### ROYAL AIR FORCE

D W I Thomas to be Squadron Leader.

Flight Lieutenant J K McCabc to be Squadron Leader.

R A Armstrong to be Flight Lieutenant.

To be Flying Officers (Temporary): D R Bowen, J S Conway, K E Cooper, F G Cumming, O W Davies, R L Edwards, G S Foster, A A Garven, M L Montagnon, W S Peart, R M McK Pratt, K J Robinson, R G H Salkeld, R H Satchell, J H Shore, B Taylor, C Taylor, A D Thom, E J Trimmer, D G Wells, and K F Wood.

### ROYAL AIR FORCE VOLUNTEER RESERVE

Squadron Leader D N Parfitt has resigned his commission. Flying Officer D V Cashman to be Flight Lieutenant.

### INDIAN MEDICAL SERVICE

Major General A H Harty C I E, has retired.

Colonel Sir David Clyde C I E, has retired.

Lieutenant Colonels A J D Souza, M C P D Chopra, K V Ramana Rao, and J Chandra, O B E, have retired, with the honorary rank of Colonel.

Lieutenant-Colonels N J U Mather, J S Galvin, W D B Reid, R C Wite and M Taylor, O B E, have retired.

Major (War Substantive Lieutenant Colonel) G S N Hughes, D S O, has retired with the honorary rank of Colonel.

Majors A W Sampey, R R Prosser, T A Cunningham, D R Hanbury, F J O'Dowd, D S O, and G J H Maud have retired with the honorary rank of Lieutenant Colonel.

Major L M Kelly, M B E, has retired.

Captains (War Substantive Majors) D F Eastcott and P W Kent have retired and have been granted the honorary rank of Lieutenant Colonel.

Captain G B Pigott has retired and has been granted the honorary rank of Major.

### COLONIAL MEDICAL SERVICE

The following appointments have been announced: A D J Farquharson, M R C S, Medical Officer, Nigeria; P F Jackson M B, Medical Officer, Uganda; W C D Lovett, M D, Medical Officer, British Somaliland; A S Moodie, M B, B Ch, Medical Officer, Hong Kong; J M Sword M B Ch B, Medical Officer, Nyasaland; F R Roberts L R C S L R F P S, Medical Officer, Gold Coast; M Sugar, M D F R C S and D W A M Degazon F R C S, Medical Officers (Specialists), Jamaica; H H Waznah M B, Lady Medical Officer, Gold Coast; A Bearblock F R C S; W G Evans, M B, W E Holmes, M B D P H, D T M & H and G H Lowe M B, D P H, Superscale Medical and Health Officers Grade B Federation of Malaya; R H Blind O B E M D M R C P I, Senior Leprosy Officer, Nigeria; S W Cooper, F R C S D T M & H, and J S McGregor, M D, M Sc, F R C S D T M & H, Surgeon Specialists, Gold Coast; G E J Porter M R C S, Medical Officer, Gambia; C R C Rainsford M D D T M, Senior Medical Officer, Uganda; B A S Russell, M D F R C P, D T M & H, Physician Specialist, Gold Coast; E A Struthers, M B, D P H, D T M & H, Deputy Director of Medical Services, Federation of Malaya; N Kerr, M B, Medical Officer, Bahamas.

## ACCIDENT AND OPPORTUNISM IN MEDICAL RESEARCH\*

BY

SIR HENRY DALE, OM, GBE, FRCP, FRS

My title speaks of accident and opportunism, and it hardly requires to be said that the two must go together if accident is to have any value, if it, indeed, is to be anything but a hindrance to research of any kind. Perhaps it is one of the important qualifications for success in research that a man should know by the subconscious reasoning which we call instinctive judgment whether what appears to be an accident, a phenomenon presenting itself quite unexpectedly, is just a nuisance, the result of some trivial error, so that the further study of it will lead to nothing but waste of time and energy, or whether on the other hand it offers a possible clue to some new discovery of real importance which ought to be followed even at the cost, perhaps, of a diversion from the original objective. The same idea has often been expressed by saying that accidents fruitful in discovery happen only to those who deserve them—to those, we may say, in whom a natural aptitude has been reinforced by stored and ripened experience, so that a trained alertness, which does not distract the attention or weaken its concentration on the chosen objective, holds the mind ready to pounce on an unexpected opportunity. If we were called upon to construct a scale of values for the different kinds of scientific research we might feel bound to accord the highest rank to the kind of investigation which can be systematically planned in advance, such as one which sets out to interpret by mathematical analysis a set of astronomical or physical data, but accidents of the useful kind have sometimes been effective even in attracting and, as it were, refocusing the attention of some of the greatest of mathematical theorists. You will remember how Archimedes, the greatest mathematician of his own and one of the greatest, I suppose, of all ages, found the clue not only to the solution of the practical problem concerning the adulteration of the gold used for the king's crown but to one of the fundamental laws of hydrostatics in a sufficiently commonplace accident—the overflowing of his bath when he lowered his body into the water. Some nineteen centuries later the young Isaac Newton driven home to Woolsthorpe from Cambridge by the arrival here of the plague, had been directing his astonishing powers to an attempt to discover a cause for the orbital motion of the moon round the earth and of the planets round the sun. Remembering later those years when he was yet only 23 to 24 years old, he wrote of himself: "I was in the prime of my age for invention and minded mathematics and philosophy more than at any time since" and on that alert and receptive mind the sight of an apple falling from a tree in the Woolsthorpe garden acts like a trigger, and it comes to him in a flash that the

gravity which pulls the apple to earth is holding the moon in its orbit, and he plunges into the calculations which, when some 20 years later they were given to the world in the *Principia* were so completely to reshape men's ideas of the universe.

I could find other examples, if we required them, of the way in which theoretical and experimental investigators in the fields of pure physics and chemistry have on occasion been able to take advantage of accidental observations to make great new advances in their various special fields. Accident certainly played some part, though probably not so great a part as popular rumour has sometimes suggested, in those great discoveries a little over half a century ago of the x rays by Röntgen and of the radioactivity of uranium by Becquerel which together contributed so much to the launching of physics into its new era. Certainly they did not belong to the same class as the discoveries which most people were expecting to arise from the natural and straightforward development of the physical knowledge of the day. I have a very clear recollection of the interest which they aroused when the news of them first came to Cambridge in my second and third undergraduate years.

Röntgen's discovery of the x rays with their remarkable penetrating properties, enabling them to pass freely through flesh and to cast shadows of the bones on a fluorescent screen, was first made known here by reports in the daily press, and I well remember a friend of some seniority telling me that he had been at a dinner party at which this reported marvel had been the prevailing subject of conversation, of which the general tone was to ridicule it as a piece of journalistic nonsense, until the only member of the party whose knowledge and judgment gave him a real title to an opinion, J. J. Thomson, broke into the babble of sceptical merriment with a strongly expressed conviction that the report would prove to be true, so far from being nonsense, it was the kind of discovery which he would expect somebody to be making soon. And then in the following year, at a meeting of the undergraduates' Natural Science Club, my contemporary, R. J. Strutt (the late Lord Rayleigh), gave us an account of Becquerel's then new discovery that salts of uranium were continuously emitting a mysterious radiation to which a photographic plate was sensitive, and I well remember the sceptical protest of one of us who was later to become world-famous in theoretical physics and astronomy. "Why, Strutt," said he, "if this story of Becquerel's were true it would violate the law of the conservation of energy!" Such a reaction may well seem strange in these days, when the senior schoolboy can tell you about Einstein's theory of the convertibility of matter into energy and its realization in the atomic bomb. But it represented then a quite reasonable orthodoxy, and

\*Being the Popular Lecture delivered on July 2 at the Annual Meeting of the British Medical Association, Cambridge 1948.

I like to remember the enterprising spirit of Strutt's rejoinder "Well, all I can say is, 'so much the worse for the law of the conservation of energy,' because I am quite sure that Becquerel is a trustworthy observer" And, of course, none of us had then any inkling of the enormous expansion of knowledge for which discoveries such as these were to provide the points of origin, or of the whole armoury of physical resources which would thus be brought to the service of medicine This is even now receiving a reinforcement of yet unmeasured magnitude from the forward leap which knowledge in nuclear physics has made in these recent years, and on the uses of which so much of the world's hopes and so much of its fears are now centred

### Medical Research

The mention of such applications to the service of medicine brings me at last to the subject of my paper—the part played by accident and opportunism in medical research, which is the field of scientific activity of which I can speak from some personal experience, and the one which we may regard as specially appropriate to this occasion Medical research as we know it to-day has spread its tentacles widely, and there is hardly any branch of experimental science now which may not find itself seized and pressed into the service, constrained to contribute from some angle, either directly or from a distance, to the scientific basis of modern medical knowledge and practice That, however, is a very recent development, modern medical research as an experimental science, or a varied group of experimental scientific disciplines, had not begun a hundred years ago, and was only just beginning to get really under way at the beginning of the present century Yet medical knowledge was making important advances at the end of the eighteenth and in the first half of the nineteenth century at the hands of the great physicians of those days, who used to the full the opportunities which they encountered by accident in their practice, enabling them to observe the regular recurrence of symptoms and conditions which others had passed unnoticed Thus the immunity from smallpox of those who had infected their hands with the cow-pox appears to have been a matter of common belief with the dairymaids and other country folk among whom Edward Jenner practised in Gloucestershire None of the other medical men of the neighbourhood, however, had observed the fact, much less recognized its significance, they even threatened, jestingly we may hope, to expel Jenner from their Convivio-Medical Club if he continued to bore them with such nonsense So he waited for many years, accumulating data as accident gave him opportunity, until at length in 1796 he followed the advice given long before by his friend John Hunter and tried the experiment, inoculating a boy with cow-pox and, when that had passed, proving him to be completely refractory to inoculation with smallpox Jenner, then, in the light of later developments may be regarded as having found already, long in advance of his time, the bridge between the method which waits for opportunistic observation to be provided by nature and encountered by accident and that which puts a possibility to deliberate test under the critical and controlled conditions of experiment And I propose now to bring to your special notice a few out of a large number of possible instances of the way in which the use of opportunity provided by accident has made contributions, some of them of the very highest importance, to the progress of medical knowledge by research even in its more recent and still flourishing experimental period

This revolutionary change in the methods of advancing medical knowledge began, as I have suggested, in the second half of the nineteenth century, and if anybody was asked to name the important factors of its beginning and its

promotion he could not fail to give to the work and the discoveries of Louis Pasteur, and to the whole science of bacteriology which grew out of them, a leading place among these factors Everybody knows that it is to the discoveries of Pasteur that we can trace the first clear recognition of living and self-multiplying micro-organisms, yeasts and bacteria, as responsible for the familiar processes of fermentation and putrefaction, and then for diseases transmitted by infection and contagion I do not think, however, that it is so generally known that accident—a whole series, indeed, of accidental and extraneous circumstances—played a very prominent part in engaging and focusing Pasteur's attention for the remainder of his life on studies which were widely divergent from the line of his original scientific interests and activities For Pasteur began his scientific career as a mineralogist and a crystallographer His first great discovery concerned the crystallography of the two isomeric forms of tartaric acid and revealed their true relation to racemic acid It was he who discovered that the two forms which in solution rotate the plane of polarized light in opposite directions have crystals with forms related to one another as that of an unsymmetrical object is related to its image in a mirror—a discovery as fundamental to organic chemistry as to crystallography, and one which might well, one thinks, have occupied the rest of his life in its direct development But a mould, a *Penicillium*, grew by accident on his solution containing both the forms of a tartrate, and Pasteur found that, as it grew, it selectively used and destroyed only the form producing right-handed rotation of the plane of a polarized beam, so that the left-rotating tartrate remained And then, with his mind thus rendered alert to the new idea of a selective fermentation as due to the action of living and multiplying organisms, Pasteur was given additional stimulus and opportunity in that direction by his appointment to a chair of chemistry at Lille, where practical problems of fermentation in the local distilling industry were waiting for his ripening genius to begin the great clarification And soon his success led to appeals to him to investigate the causes of the variable results encountered in the fermentative production of vinegar and in the brewing of beer, and he was summoned then to deal with the diseases of wine in his own native countryside, and in every case he was able to identify and to separate the micro-organisms responsible for the desired fermentation and to show the way to eliminate those which diverted it harmfully And then, of course, his success with the diseases of wine involved him in insistent pleas that he would direct his researches to the elimination of the infectious disease known as "pébrine" from silkworms And thus the train was laid for the great revolution in the pathology and eventually in the treatment of infectious diseases through the further work of Pasteur himself and his immediate pupils in Paris, of Koch in Germany, of Lister in this country, and of all the great host of their disciples and followers throughout the world, right down to the present day, who have caught and carried forward the flame first kindled from the interest of a man of genius in the crystallography of the tartaric acids and in the accidentally observed effect of a mould which grew on them

### Beginning of Endocrinology

As another leading factor in the great change which has come over the whole aspect of medical knowledge and research we should certainly mention the rise of experimental physiology and, later, of biochemistry And among the special fields of investigation in the general domain of these, which have had a specially direct influence on knowledge of diseases and their treatment, we might well mention those concerned with the hormones and the vitamins And here again, if we look at the beginnings of experimental

activity in both these fields, we shall find the exploitation of happy accident playing a part of real importance

The real beginning of scientific endocrinology, the study of the internal secretions or hormones, may be found, I suppose, in the brilliant use which great English physicians of the middle of the nineteenth century made of their opportunities, presented by accident, for accurate observations at the bedside and in the post-mortem room when Thomas Addison described the malady known by his name and recognized its regular association with destructive disease of the suprarenal gland, and when William Gull described myxoedema as a kind of adult cretinism and traced it to atrophy of the thyroid gland. But nobody in 1889 had any idea that the much commoner disease diabetes mellitus had any connexion with the defect of a gland or the lack of an internal secretion. In that year Professor von Mering, of Strasbourg, asked his assistant professor, Minkowski, to remove the pancreas from a dog by operation in order that they might study the absorption of fat from the intestine in the absence of that gland. So, purely by accident, it was discovered that the dog without a pancreas showed an abnormal hunger and thirst and passed large volumes of urine, which Minkowski found to be loaded with glucose. Naturally he turned aside to investigate the condition more closely, and point by point he found it to correspond with a severe diabetes mellitus as this had long been known in the human patients whom it afflicted. But more than thirty years were to pass before this discovery was made fully effective for medical practice by the determined enterprise of two young Canadians, Banting and Best, who, after many experienced investigators had failed, demonstrated the possibility of preparing the missing hormone, insulin, from the pancreas and therewith changed completely the prospect of the sufferer from diabetes. More than that, I think, that it cannot be doubted that the stimulus due to Banting and Best's success was an important factor in the astonishing advance which research began at once and continues still to achieve over this whole field of knowledge of the endocrine glands and their hormones. Let me mention just one item. But a few years ago the disease known as pernicious anaemia, or sometimes as Addison's anaemia, was as completely beyond the reach of effective remedy as diabetes had earlier been, when a team of physicians in Boston (Mass.) discovered that a hormone could be prepared from the liver by the use of which the prospect of the sufferer from pernicious anaemia has been transformed as completely as that of the sufferer from diabetes by insulin. The senior member of that Boston team, Professor Minot, is himself a sufferer from diabetes, and insulin had come just in time to save him from a premature death and to fit him to take a leading part in the discovery which is now saving others from pernicious anaemia. Is it fanciful, then, to find in Minkowski's enlightened use of the opportunity which accident offered him in 1889 the real starting-point for work which has now led to the effective treatment of more than one disease regarded till a few years ago as beyond any hope of remedy?

#### Nutrition and Biochemistry

There has been a good deal of discussion, in an entirely friendly spirit, concerning the real starting point of the researches which led to the recognition of the vitamins and thus to the specific and effective treatment or prevention of a number of other formerly mysterious diseases now known to be due to the lack of one or another of these trace-constituents of a normal diet. There is one accidental observation used to remarkable purpose by the late Sir Frederick Gowland Hopkins which must, I think, be regarded as the first link in a chain of discoveries by which that great investigator was led to his first recognition

of the factors which we have come to call the vitamins. One student in Hopkins's early advanced class at Cambridge, the late John Mellanby, who was long afterwards the distinguished occupant of the Oxford Chair of Physiology in succession to Sherrington, was curiously unable to obtain the colour reaction for proteins which a certain Adamkiewicz had described, and Hopkins himself found that with the particular bottle of acetic acid on Mellanby's shelf it was indeed unobtainable, though that from all the other bottles in the laboratory gave it readily. He did not put the matter aside as one of those queer anomalies and content himself with telling Mellanby to borrow the reagent from his neighbour, he recognized, with his remarkable instinct, that here was something of potential importance, and with the assistance of another member of the class, S. W. Cole, he immediately began the investigation which led them to the discovery that the reaction was due to glyoxylic acid, which almost all specimens of acetic acid contain as an impurity. Then, with a more effective reagent, they were able to isolate the constituent of proteins giving this and another well-known colour reaction and to identify it as a new amino-acid, tryptophane. And then Hopkins undertook experiments to determine the degree to which each of the different amino-acids which had then been identified, tryptophane among them, was a necessary constituent of a diet for maintenance and growth, and thus he was led further to the discovery that young rats could not grow, or even maintain their weight on food made up from all the known constituents of a complete diet in abundance if these had been elaborately purified. So it was made clear that there were unknown factors of a normal diet, minute in quantity but essential to make the food adequate in quality for normal nutrition, and biochemistry was launched upon what soon became a world-wide expedition of research, still in progress, in pursuit of the vitamins.

Many of you, I think, will have heard of "Ringer's solution"—a watery solution of salts in carefully adjusted proportions with which the late Dr. Sidney Ringer was able to maintain the heart removed from the body of a dead frog in vigorously beating activity for hours. Ringer was a physician to University College Hospital, and, in such time as he could spare from his practice, one of the pioneers of pharmacological research in this country. In his early experiments he had found that a solution containing only pure sodium chloride, common salt, in the proportion in which it is present in the serum of frog's blood would keep the beat of the heart in action only for a short time, after which it weakened and soon stopped. And then suddenly the picture changed: apparently the same pure salt solution would now maintain the heart in vigorous activity for many hours. Ringer was puzzled, and thought for a time that the difference must be due to a change in the behaviour of the frog's heart with the season of the year—until he discovered what had really happened. Being busy with other duties, he had trusted the preparation of his solutions to his laboratory boy, one Fielder, and as Fielder himself whom I knew as an ageing man, explained to me, he didn't see the point of spending all that time distilling water for Dr. Ringer, who wouldn't notice any difference if the salt solution was made up with water straight out of the tap. But, as we have seen, Ringer did notice the difference, and when he discovered what had happened he did not merely become angry and insist on having distilled water for his saline solution, he took full advantage of the opportunity which accident had thus offered him and soon discovered that water from the tap supplied then to North London by the New River Company, contained just the right small proportion of calcium ions to make a physiologically balanced solution with his pure sodium chloride, and when, guided by

further analysis, he had also added the correct small proportion of a potassium salt, Ringer's solution was complete, and with the later modifications which Locke, Tyrode and others introduced to make it suitable for the tissues of other animals it has become an essential reagent for everyday use in an immense range of medical and biological research procedures

### Adrenaline and Acetylcholine

Some fifteen years later another observation, also of far-reaching effect on the progress of physiology, was made in the same laboratory at University College in circumstances which, if not entirely accidental, had at least something of that character. Dr George Oliver, a physician of Harrogate, employed his winter leisure in experiments on his family, using apparatus of his own devising for clinical measurements. In one such experiment he was applying an instrument for measuring the thickness of the radial artery, and, having given his young son, who deserves a special memorial, an injection of an extract of the suprarenal gland, prepared from material supplied by the local butcher, Oliver thought that he detected a contraction or, according to some who have transmitted the story, an expansion of the radial artery. Whichever it was, he went up to London to tell Professor Schafer what he thought he had observed, and found him engaged in an experiment in which the blood pressure of a dog was being recorded, found him, not unnaturally, incredulous about Oliver's story and very impatient at the interruption. But Oliver was in no hurry, and urged only that a dose of his suprarenal extract, which he produced from his pocket, should be injected into a vein when Schafer's own experiment was finished. And so, just to convince Oliver that it was all nonsense, Schafer gave the injection, and then stood amazed to see the mercury mounting in the arterial manometer till the recording float was lifted almost out of the distal limb.

Thus the extremely active substance formed in one part of the suprarenal gland, and known as adrenaline, was discovered. And in due course there came to light the curious correspondence between the effects produced by this potent substance and those produced by nerves of the so-called sympathetic system, and Professor T. R. Elliott, then a postgraduate research student in Cambridge, was led to make the brilliant suggestion that these sympathetic nerves produce their effects by liberating small quantities of adrenaline at the points where they end in contact with muscle fibres and gland cells. Some ten years later it came to my notice by sheer accident that a particular extract of the drug known as ergot of rye exhibited a curious and very potent type of activity. With the co-operation of my chemical colleague at the time, Dr Ewins, the substance responsible was isolated from the ergot extract and identified as the acetic-ester of the base choline, acetylcholine. And when the actions of this came to be examined in detail they showed as suggestive a correspondence to the effects of other nerves as those of adrenaline had shown to the effects of the sympathetic nerves in particular. At that time there was no reason at all to believe that acetylcholine was a natural constituent of the animal and human body, but my late colleague, Dr Dudley, and I found it there some 15 years later, again by accident, when we were looking for something else. And meanwhile my friend of many years, Professor Otto Loewi, then of Graz but now in New York by experiments of a most elegant simplicity had directly demonstrated, in confirmation of Elliott's much earlier suggestion, that impulses passing down the fibres of different nerves to the frog's heart do in fact produce their effects by liberating at the junctions of the nerve with the muscle fibres one or the other of two substances, and these two

substances were found to be identical with adrenaline and acetylcholine in all the properties for which they could be tested. And further developments, in which I have again taken a part, entitle me to believe that even at this moment impulses passing down nerve fibres are liberating tiny charges of acetylcholine where these fibres end in the muscles of my tongue, my lips, my larynx, and my diaphragm and are throwing these into the complicated and varying patterns of speech, which, I hope, contrives none the less to be reasonably articulate.

### Histamine and Penicillin

The intimacy of direct experience may to some extent justify this mention of incidents involving my own activities alongside the examples of the far-reaching importance of the part which accident may play in medical research which I have cited earlier. If further excuse is needed, I may plead that the function of acetylcholine as a transmitter of nervous effects figured prominently in a discussion meeting held here yesterday in one of the scientific sections of the British Medical Association. There is even something of the nature of an accident in the fact that this morning another of the sections had a discussion on a novel group of remedies called "Antihistamine substances", for histamine is another base which came to my notice by accident, some 40 years ago, as accounting for the special activity of another kind of extract from the same curious drug, ergot of rye. When histamine had thus been isolated and identified by my late colleague, Professor George Barger, it proved to have an action reproducing most of the symptoms characteristic of an "anaphylactic" or "allergic" reaction—a type of reaction which will be familiar to most of you in the special forms of hay-fever, nettle-rash, and some forms of asthma. Then I had another stroke of luck. I was studying a rather weak activity of a similar kind which fresh blood serum exhibited when it was applied to strips of involuntary muscle taken from a dead guinea-pig, and I suddenly encountered a strip of this tissue from one particular guinea-pig which responded with a contraction of peculiar violence when it was treated with a mere trace of horse serum, though it behaved quite normally in the presence of blood serum from other animals—cat, dog, rabbit, sheep, or man. And it occurred to me that many guinea-pigs in that laboratory were used for testing the strength of antitoxic horse serum, and that an economically minded colleague might have provided me with a survivor from such a test. The verification of that suspicion gave us a new idea about the meaning of the anaphylactic or allergic condition, but it took many years more, and a great deal of work in many laboratories in different countries before we were able to establish the fact that histamine is a natural constituent of most cells of the living body which is normally held harmless and inactive in their interior but is released, so as to produce its characteristic effects if the living cells come into contact with some substance from a plant or animal—grass pollen, scurf from a skin, and so forth—to which they have become abnormally sensitive or allergic. And now, here in Cambridge, only this morning we have been discussing the action of "antihistamines"—substances for which it is claimed that they relieve the symptoms by preventing the action of histamine when this is set free by the effect on allergic cells of the substances for which they have acquired a specific sensitiveness.

There is one more example which I must mention, even if only because it will certainly, and most properly, be already in the minds of many of you—the discovery of penicillin. The contamination of a bacterial culture growing upon a plate of solid nutritive medium by the spore of a mould falling on it while the cover is removed for examination must be a frequent and usually no more than a mildly

annoying incident of bacteriological practice. It was the chance coincidence of three conditions which made its occurrence on a particular plate in 1929 the starting point of a discovery of first-rate importance. (1) The contaminating spore was that of one particular mould species, *Penicillium notatum*, (2) the culture on the plate was that of a staphylococcus, susceptible to the restraining effect of an antibacterial agent which this mould produced, and (3), most important of all, the worker concerned was Professor Alexander Fleming, with the eye of a medical naturalist, alert to detect the unusual phenomenon of a kind of halo round the spot where the mould colony grew, free from colonies of the staphylococcus which grew abundantly over the rest of the plate. Sir Alexander Fleming, as you know, picked off the mould colony and cultivated it in a broth, and found that the broth contained an antibacterial agent which he named penicillin. Then, as happened with Minkowski and the pancreatic hormone, neither Fleming nor anyone else for some years could hold out any hope of the chemical isolation or even of a substantial purification of penicillin, to say nothing of its eventual production in a form and in a quantity enabling its therapeutic possibilities to be critically tested. Such a possibility had in fact been practically written off the account and almost forgotten until, like Banting and Best with insulin, Sir Howard Florey and his chemical collaborators took it up with determined energy and with brilliant and resourceful enterprise, and now the research chemists and the organized therapeutic industry of half the world have combined to exploit and develop this gift of an alert opportunism and to make it a practical reality for human need. And the chemists have isolated several penicillins, determined their constitutions, and even made one of them by synthesis. And this success has had value not merely for its own sake, it has opened up a most hopeful vista of other and perhaps equally important discoveries in the same field, streptomycin, chloromycetin, and others yet to come.

Of course there are plenty of other instances to be found of opportunity coming to an attentive worker in research through what we have to regard as chance or accident, and, apart from the many which could be collected, there must be innumerable cases which will never be recognized because no record of them has been preserved. I hope, however, that my choice of a subject and citation of examples will not bring me under the suspicion of suggesting that accident is the principal factor of success in research of any kind, or of medical research in particular. Accidents of the kind which we have been discussing do not, in fact, happen to the merely fanciful speculator who waits on chance to provide him with inspiration. They come rather to him who, while continuously busy with the work of research, does not close his attention from matters outside this principal aim and immediate objective but keeps it alert to what unexpected observation may have to offer. I certainly do not believe that any research work of permanent value is done, or any discovery of importance soundly established without a great deal of hard systematic, and conscientious work.

Then I should not like to be misunderstood as suggesting that mankind would have been left in permanent ignorance of any of the items of scientific knowledge great and small which I have cited through default of the accidents which were in fact associated with their discovery. If Archimedes' bath had failed to overflow or the falling apple to catch Newton's attention the principles which they gave to the world would not have remained hidden for ever and probably not for long. We know in fact that Hook and Wren and Halley were actually competing in speculation about an inverse-square law of gravity and the moon's orbit without being able to calculate the relation,

and that it was the news, indeed, of such an approach to its independent discovery which acted as a stimulus to Newton, leading him to publish at last what he had known in principle and worked upon intermittently for over 20 years. We cannot be so certain in other cases but it does not seem likely that the effects of removing the pancreas, or of injecting a suprarenal extract into a vein, would have remained very long unknown even if von Mering had not called on Minkowski to perform the one for another purpose, or if Oliver had not goaded a reluctant and sceptical Schafer into trying the other. Incidents of the kind which I have described may greatly advance the date of a discovery or may associate it with the name of a particular investigator, but I do not believe that they will ever produce discoveries which would not eventually be made without them. They may provide, however, touches of high-light in the varied landscape of science, of decoration to its solid building, or of light relief to the more serious drama of its normal and logical advancement. And if they have thus lent something of life and colour and everyday interest to an hour of talk about medical research they have helped me to achieve a large part of my intention.

## THE PROBLEMS OF CLINICAL RESEARCH

BY

L J WITTS, MD, FRCP

*Nuffield Professor of Clinical Medicine Radcliffe Infirmary Oxford*

First-class clinical research has been and is being done by men busily engaged in practice. For examples in my own generation I think of J W Brown's work on congenital heart disease, Cookson on thyrotoxicosis, or Sheldon on haemochromatosis. In a delightful article called "Clinical Research with a Notebook" Alvarez (1946) has illustrated the good research work done by what he calls small-town doctors. The man in practice has the best opportunity of carrying out clinical research in depth, the intimate and prolonged study of people to learn what happens to individuals with certain constitutions or chronic diseases. If in the rest of this article I refer to clinical research by whole-time workers in hospitals or institutes it is not that I forget these facts but rather that I am addressing myself to those who wish to make clinical research their career or major interest and to those who should provide the facilities for them. I must ask to be excused, likewise, for quoting examples from the work of my own department.

Simon Flexner (1939) said that one of the essentials for successful clinical research was the power of the researcher to command his time for the patients, from whom the research problems are derived, and for the laboratory, in which those problems are investigated. No man in a busy practice can command his time, and for this reason great men like Richard Bright have found it impossible to continue clinical research when they have made a name in practice. The young man who wishes to engage in clinical research in this country should usually work whole-time in a hospital or a research institute. The opportunities for this type of employment have been greatly enlarged by the increased funds which are now at the disposal of the University Grants Committee and the Medical Research Council. Nevertheless, whereas medical practice may be regarded as a stairway, in which the opportunities do not diminish as a man advances in years, the academic and research

career will always be like a pyramid, with more room at the bottom than at the top

### A Recurrent Suggestion

Running through discussions on the new health service like a strand in a rope there is the recurrent suggestion that improved organization of medical care and the formation of regional boards will lead to better facilities for clinical research. One hopes this will be true, but there are reasons for not being too sanguine. There is an immediate danger that senior clinical research workers will be overwhelmed with administration and that juniors will be tempted away by the high salaries of young consultants. There will be obvious gains if notes are better codified and if we can register sickness as exactly as we can register the number of people in the country, their births, marriages, and deaths. The burden of filling in forms is so heavy, however, that I hope our statisticians will not try to do too much at once. A vast amount of time and labour can easily be spent on records, and research of this kind needs to be carefully planned and costed if it is to yield an adequate return. Democracy begins at the grass roots, and more willing co-operation will probably be obtained if the regions are given specific tasks, as in the notification of jaundice in Region IV during the war. This, however, is social medicine rather than clinical research in the ordinary sense.

There is likely to be increased concentration of cases in special centres, like the centres for head injuries, chest diseases, and gastric complaints which were started under the EMS in the war. On a short-term basis this undoubtedly leads to technical advances, particularly when physicians and surgeons work together on common problems, but it is like farming for cash crops and the output soon seems to dwindle. Moreover, the advances are almost entirely technological and self-limited, unless the centres are designed as research units, as Colebrook's burns unit and some of the malaria research units were. Pupils of mine who have worked in units which were primarily designed for research on a single disease have nevertheless spoken of their anxiety to get back to general medicine after a time to refresh their minds. Special clinics for asthma, rheumatism, and anaemia tend to develop a routine and research fades into the background. Just as the best farming is mixed farming, so the best clinical research is likely to be done in general hospitals, particularly those which are so fortunate as to be associated with university scientific departments. The chief stimulus to clinical research in the new health service will probably be the creation of more full-time specialists. Much has been done by such men under the old regime, as, for example, Avery Jones on gastro-duodenal ulceration, Banks on cerebrospinal fever, and Anderson and his colleagues on pneumonia.

How clinical research units or institutes should best be organized is still not settled. In university departments research must usually be combined with teaching. I have been convinced by my own experience, and that of other clinical researchers and whole-time teachers in this country and America, that it is not possible to research or teach on other people's patients and that whole-time academic workers and part-time consultants do not mix. I know that the rational answer is that the practising clinicians should "feed" the academicians, but owing to the loyalties and antagonisms which develop among groups of human beings this rational solution does not work. Whole-time and part-time clinicians are much better friends if they work in separate compartments. The clinical research workers must control their own group of patients. It is this necessity to

combine research with the treatment of patients which differentiates clinical research from all other forms of medical research and poses problems to which there are as yet no generally accepted answers.

### Size of the Research Unit

The first problem is how large a clinical research unit should be. Sir Thomas Lewis believed that the number of beds in a university department of medicine should be small—20 or 30. I worked for eight years with a department having only 21 beds, and I am sure Lewis was wrong. Lewis's own small research unit was superimposed on a much larger whole-time general medical unit, with which he worked in a particularly happy association. The total number of beds was in fact over 50. Lewis talked vaguely about a pool, but whereas one can pool ships and merchant seamen in wartime (even then there are complaints) one cannot shuttle patients about in this way. Our fellow countrymen are sensible of the needs of clinical teaching and research, but they will not tolerate the conception of patients as clinical material which can be moved hither and thither at our convenience. The physician who is in practice acquires obligations to his patients and their general practitioners which make it hardly possible for him to hand them over to the care of another. Yet without complete control clinical research may be frustrated. On the other hand, the conclusion of any research project such as the study of special diets in hepatitis or the treatment of rheumatoid arthritis by the induction of jaundice leaves a responsibility for a large number of chronically ill patients which cannot be summarily abrogated. Just as the practising physician cannot hand over cases for research without qualms, so the clinical research worker cannot expect his colleagues to look after patients he has tired of. Finally, senior clinical research assistants must have the opportunity at times of exercising major clinical responsibility. If they do not, they will move at an early age to another post. Constant changes of staff on this account crippled the research of the London University professorial units in the inter-war years. In the language of the cinema, the professor was degraded from director to continuity girl. All this means that the unit must contain four or five times as many beds as are theoretically necessary for research.

Latterly I have been working with a total of 45 beds in two units, unfortunately geographically separate, of 21 and 24 beds respectively. The smaller unit has been used for acute illnesses, complicated cases, and clinical research. The larger unit has been used for routine work, for cases requiring protracted treatment, and for neurology. There has been little undergraduate teaching. These 45 beds, with their associated out-patient and follow-up clinics, have provided the background for a staff of six senior colleagues and a further six juniors of registrar status. With such a staff it is possible for all members of the department to have short periods of concentrated clinical work and longer periods when they have adequate leisure for research. No one is ever responsible for the supervision of more than 21 beds but this is quite enough for one man to look after when investigation and research are being carried out at high pressure. We have plans for a unified department of 64 beds, and I believe that a unit of 50 to 100 beds, subdivided on functional lines and with a staff large enough to allow of alternation between research and routine clinical work, should provide the best solution of this difficult problem (Gardner and Witts, 1946).

The great danger in a unit of this size is the tendency to fritter. The world of medicine is so full of interesting and distracting things that we are tempted to diffuse our energies

over all of them instead of concentrating on one problem. It is this tendency which has made the words "clinical research" and "clinical pathology" an offence in the nostrils of the preclinicians, who regard us as expensive butterflies rather than worker bees. This is at bottom a difference of philosophies. One school teaches that every patient must be regarded as nature's experiment from which something new can be learned. All mysterious and bizarre cases, particularly if they affect the bones or the endocrines, are inevitably classified as professorial cases. The other school teaches that the clinical researcher must at all costs narrow his field of vision and draw an absolute distinction between research and the routine practice of medicine. I am sure that this is right. Once we give way to the temptation of following every interesting problem that presents itself at the bedside we shall be like the centipede counting its legs. In the ward one must constantly put a blind eye to the telescope. I am adamant on the rule that you can't research on all the diseases all the time.

### Training

The next question is that of training. The key word in clinical research is *clinical*. The clinical scientist must be a properly trained clinician or no hospital committee will give him charge of beds. Nothing is more disastrous than for a man to take up clinical research and find himself in the thirties without a proper label, recognized neither as clinician nor as scientist. In the United Kingdom the clinical label is the M.R.C.P., preferably taken three years after qualification, after say two years in house appointments and a year working for the M.D. From the beginning, therefore, the clinical researcher is handicapped in comparison with the researcher in the basic sciences, who can begin a research career immediately after qualification. But a clinical training will not make a man a researcher—in fact, in some ways it unfits him by encouraging a superficial, know-all attitude. A man cannot get far in clinical research to day without some special knowledge of experimental pathology or chemistry or physics or statistics. He must have another string to his bow. There is little doubt that at this stage of his career a man should spend a year in a non-clinical department, not merely to refresh his basic knowledge but even more to learn how problems can be isolated and how knowledge can be advanced by patient work and by learning to take one step after another. Technical equipment can be picked up by the way. What cannot be picked up is faith in the scientific method, in the value of experiment in the ability to master technical procedures, in the necessity to concentrate on one purpose. All this is so different from the atmosphere of a busy ward where many tasks must be carried out simultaneously and where judgments must be made and acted on immediately that it is hard for a man to acquire a real faith in the scientific method without a period of isolation from patients.

Clinical research is inevitably a compromise between the desire to practise medicine and the desire to advance knowledge. As such it makes the clinical researcher suspect to the practising physician as well as to the pure scientist. With some of my colleagues it is an article of faith that a clinical scientist cannot be a good doctor. This is really a rather foolish controversy but it is the sort of thing that happens when practising clinicians who are individualists work alongside clinical research workers who should be team workers. I will merely turn the argument and say that the clinical scientist need have no false shame about asking for advice whereas I have known honorary physicians who would have cut off their right hands rather than sign a request for consultation from a more expert colleague. The practising clinician should be superior in

manual dexterity, though the clinical scientist can, if he wishes, concentrate on one technique or operation. The only charge which requires an answer is that the clinical scientist studies diseases while the practising clinician treats patients. If research should lead to neglect of the patient as an individual, then indeed the head of the department would be open to serious criticism. A genuine affection for patients is a prerequisite for a man in such a position.

### Technical Problems

The technical problems of clinical research at the present time are those of research in general and of clinical research in particular. They depend partly on specialization of knowledge and partly on the need for workers, equipment, and buildings on a lavish scale. Within the narrow field of haematology there are now particular groups which talk a language that is almost incomprehensible to other haematologists. The workers on the rhesus factor, on blood coagulation, and on the macrocytic anaemias have each developed a body of data and hypotheses which needs a man's whole attention to keep up with. It is difficult if not impossible to make further progress in these subjects without a special knowledge of genetics, physics, or chemistry.

Here we meet one of the logical problems which face the clinical research worker who by luck or good management gets in on the ground floor, as it were, at the beginning of some new advance. Good examples in recent years are the effects of vitamin K and dicoumarol on blood coagulation, and the rhesus factor. As soon as a new idea like this is out of the bag the laboratories of the world, particularly its western hemisphere, are after it like a pack of hounds. The pace of advance is breath-taking. Pretty soon our clinical scientist must decide whether he is going to dedicate his life to a single pursuit, as Price-Jones dedicated himself to the measurement of red cell diameters and Ponder to their lysis, or whether he is going to remain the unspecialized researcher. This is a difficult and an individual decision. My own view is that just as the key word in clinical research is *clinical* so the proper contribution of the clinical scientist is that of the *holist*. Once research gets down to fundamental problems of chemical structure or enzymology or radioactivity it is probably better handed over to people trained primarily in those subjects. At this level the clinical research worker may act as one member of a team, but he can rarely get far under his own power.

What is quite certain is that it is unwise for the man with a clinical training to start researching in a rapidly moving subject unless he really does get in on the ground floor. It is different, of course, if the entry to the subject is restricted by shortage of supplies, as in the case of penicillin and streptomycin, and he is one of the favoured ones who is asked for clinical trials. I have known a number of promising men who have had a good line of their own and yet have never been able to resist the fatal attraction of new discoveries and have fluttered off to them like moths to a candle. The usual result is a repetitive article in one of the journals, not infrequently there is a coldness on the part of the original discoverer, and sooner or later people, remembering his own particular subject, begin to ask, "I wonder why X never got on with so-and-so" he seemed to have the ball at his feet a few years ago."

### The Law of Diminishing Returns

It is difficult to see any end to research in the basic sciences, certainly the sky is no longer the limit. The field of clinical observation, however, is subject to the law of diminishing returns. The descriptions of the signs,

symptoms, and morbid anatomical appearances of disease made in the first fifty years of the nineteenth century were more numerous and striking than those which have been made in the twentieth. Apart from coronary thrombosis and subarachnoid haemorrhage, it is difficult to think of any important diseases which have been discovered with the unaided senses at the bedside and the necropsy table in our generation. It is still possible to paint fresh pictures of disease in the tropics and in industry, but so far as ordinary clinical work is concerned the methods of Bright and Addison have yielded their harvest and only a few ears like temporal arteritis and bronchial adenoma remain for the gleaners. The recent advance has come from the application of the techniques of microbiology, chemistry, and physics. As a general rule it is unwise for the whole-time clinical research worker to take up projects which demand personal supervision of large numbers of patients. That kind of work is much better done by the full-time specialist (Avery Jones, 1948). Just as the full-time specialist cannot afford to get too far away from the bedside, so the academic physician or clinical scientist cannot afford to be too long away from the laboratory.

For clinical research to be profitable it must follow the sequence of observation, hypothesis, experiment. Experiment may be carried out in man or animals. The difference between the clinical scientist and the experimental pathologist in the use of animal experiment is hard to define, but it is nevertheless real. It depends on the fact that the clinical scientist is in close contact with patients and therefore tends to use animal experiment, and indeed all other scientific techniques, for the solution of immediate problems. Just as medicine is the mother of the sciences, so to-day those sciences are continually making fresh contributions to the support of medicine. There is a never-ending task in adapting new techniques and discoveries to the solution of clinical problems. The application of induced radioactivity and radar to the study of disease in man is the latest example of this process.

### Experiment in Man

As new drugs are discovered they require trial in man, and the same applies to techniques as diverse as the punch card and the electro-encephalogram. Pharmacological experiment in man has given us new substitutes for morphine and new treatments for insomnia, epilepsy, and migraine. Similar studies may well lead us to the control of other common mental ills such as anxiety and impotence, depression and brooding. There is much to be done in psychiatry, genetics, social and industrial medicine, and demography. Many forms of rheumatism, and some aspects of the allergic and the psychosomatic diseases, can at present be studied only in the human subject. Our lack of progress in the control of these diseases and of mental disorders in general nevertheless emphasizes the difficulty of studying disease in man without the aid of animal experiment. How easy it is to aver that mental ideas or states can be converted into physical disease processes as they can be converted into phobias or hysterical paralyses, but how difficult it is to prove it or to demonstrate the mechanism! This is certainly a field which no one but the clinical researcher can enter at the present moment. The reason work has not got much beyond the descriptive or speculative stage is because of its extraordinary difficulty. Nevertheless, the work of Selye on the alarm reaction, Wolff and Wolf on pain, Lewis on urticaria, and Macfarlane on fibrinolysis does suggest some methods of attack.

Deliberate experiment in man is a relatively recent development, and I should like to say something about the

ethical problem. I have had practical experience of therapeutic trials in pernicious anaemia, of exposure of human volunteers to TNT and to mepacrine, and of the induction of infective hepatitis in man. Each of these experiences has occasionally caused the most lively apprehension. There is no evidence that anyone died or became permanently ill as a result of the numerous successful transmutations of jaundice to human volunteers during the war, yet this method of approach has for all intents and purposes been abandoned. It is not just that the volunteer is sometimes an unstable person who may swing violently from co-operation to antagonism; the plain fact is that few researchers would willingly inoculate themselves with jaundice, and it is an absolute rule of clinical research that one should never do to others what one would not do to oneself. Once break this rule and one is on the slippery slope that led so many Nazis to the abyss. Moreover, it is a moot point whether a healthy citizen is within his legal rights in volunteering for a dangerous experiment, any more than he has a right to bequeath his body. Certainly, the complications as regards inquests and sickness and life insurance are formidable. For all these reasons dangerous experiments on healthy researchers or volunteers are rarely wise in peacetime.

Therapeutic trials and investigations on sick people are on a different footing, for every treatment is an experiment and every potent remedy is dangerous. Nevertheless, here also one must stick to the rule of doing as one would be done by. All of us know surgeons, physicians, and investigators who have got a reputation for ruthlessness. This was never a good thing, and it is probable that it will be anathema in the new health service and under the present egalitarian regime. Even such relatively safe procedures as the deliberate provocation of attacks of angina or epilepsy, or the study of the failing heart by catheterization and angiography, have come in for lively criticism. The only justification for experiments on patients is that the information cannot be obtained from animals and that it is likely to be of benefit to the patient and his fellow-sufferers.

Mackenzie and Lewis both held that the study of symptoms in man would be as profitable as the study of physical signs and post-mortem appearances in the nineteenth century. So far it has proved unproductive. Indeed, I believe that they did English clinical science something of a disservice, and that the great weakness of our clinical research, in surgery even more than in medicine, is its failure to turn instinctively to animal experiment. The work of Himsforth on hepatitis or of my own co-workers on macrocytic anaemia is the type of procedure we should encourage. The problem, a clinical problem, arises in the ward and it is studied under simplified conditions in the experimental animal. Perhaps at this point I should confess my opinion that clinical science is essentially an applied science and therefore clinical research should be practical. Too great a concentration on the human subject leads to work which may be elegant but which gives a poor return for the talent and effort devoted to it. Much of the work which has been done on renal function and on the peripheral circulation in man seems to me to come into this category. One feels *a priori* that this is not the right approach to the prevention and treatment of nephritis or vascular disease.

The happy warrior, of course, is the man who, like Adrian, is equally at home with human or animal experiment and who uses each for the purpose for which it is most appropriate. So let me make it clear that I am not trying to advise the clinical researcher to work on animals rather than men, but that I am emphasizing the importance of the experimental method. In the address I have previously quoted, which was given on the foundation of the Nuffield

Clinical Chairs in Oxford, Flexner said that the key to achievement lies in the laboratory. It is not merely that the laboratory contains instruments of precision and that work can be carried out on animals, but the laboratory implies experiment. Above all, laboratory experiment means that fixed times and days are consecrated to research, and there is not the same danger of allowing research to be swamped by routine or to be relegated to the evening hours when the real work of the day has been done, as so often happens in clinical research.

### Conclusion

The power to command one's time—that is the root of the matter. Unless clinical research is strongly buttressed by the laboratory and the experimental method it may be swept away and submerged by the oncoming tide of hospital organization. I am prepared to interpret the concept of the experimental method broadly, and I accept the view that there may be valuable psychological and sociological techniques which differ from the classical methods of experiment. All I wish to emphasize is the need of time and space for the pursuit of knowledge in the field of clinical medicine. The university clinical departments were diverted from research to teaching after the first world war, and there is a real risk that they may be diverted to regional organization after the second. If the new health service makes excessive demands on the universities for technical and administrative help clinical research will suffer. There are too many people in influential positions in this country who act as if they believe that clinical research is useful as an intelligence test to decide whether a man is energetic and clever enough to be appointed to a chair or the staff of a hospital, but that it should not engage his time thereafter. The fact that a single clinical scientist like Colebrook can do more for the relief of suffering in obstetrical and surgical emergencies than a hundred practising specialists or administrators makes little impression. What one misses in the United Kingdom, in contrast to the United States, is an abiding faith in clinical research as the most important business in which a hospital can be engaged. Until that belief becomes more widespread we may have an efficient apparatus for the treatment of disease by orthodox methods, but we shall never in the literal sense of the words have a health service.

Gardner F., and Witts, L. J. (1946) *Lancet* 2, 392.  
Jones F. Avery (1948) *Ibid.* 1, 433.

The Council of the Faculty of Ophthalmologists has reported that the Ophthalmic Subcommittee of the Negotiating Committee met representatives of the Ministry of Health on two occasions to consider the fees for the testing of sight under the Supplementary Service. As a result of these negotiations the Ministry agreed to the payment of £1 11s 6d per case, on the condition that the work would be carried out on premises and with equipment provided by the ophthalmic medical practitioner. The question of general-practitioner ophthalmologists caused some difficulty, and the fee was fixed on the understanding that not less than 95% of the work would be carried out by ophthalmologists of specialist status. The Ministry agreed that specialist status should include any doctor who held an ophthalmic diploma, even though he might be engaged in general practice. The remuneration of medical officers carrying out refractions in hospital has also been considered by the council, which has reiterated its opinion that the Supplementary Service should not be carried out in hospital, and has agreed that remuneration for refraction work in hospital should be on a sessional rate, based on the Spens Report. It has been decided to take the matter up with the Ministry of Health, together with various other points, including the establishment of the ophthalmic subcommittees of the regional boards, the position of the dispensing opticians in hospitals, and the employment of refracting opticians in hospitals.

## MEDICAL RESEARCH IN THE LABORATORY

BY

Sir CHARLES HARRINGTON, M.A., Ph.D., F.R.S.  
*Director of the National Institute for Medical Research*

In attempting to present a picture of medical research in the laboratory as it is understood to-day it is very difficult to define the limits of the field. There was a time not so very long ago when an institute for laboratory medical research could be considered reasonably complete if there were adequate representation within it of pharmacology, pathology, and bacteriology. Now, on the other hand, we are approaching, if indeed we have not already reached, a state of affairs in which any sort of scientific discipline may be called upon to contribute to the solution of a medical problem.

The trend of development may be illustrated by what has happened at the National Institute for Medical Research. The Medical Research Council has always taken the broadest view of the range of activities which should be embraced by medical research. Nevertheless, when the National Institute for Medical Research was opened in 1920, with the avowed intention that it should house the principal scientific activities of the Council, only three groups of experimental laboratories were set up: these were laboratories for physiology and pharmacology, pathology and bacteriology, and applied physiology.

It is true that from the first the scope of the activities included under these headings was very wide. Within the division of physiology and pharmacology, for instance, the work ranged from synthetic organic chemistry to pure physiology. Nevertheless, the picture was a very different one from that presented by the National Institute for Medical Research to-day, in which most branches of scientific work are represented and in which more and more importance is attached to those branches which at first sight have the least immediate contact with practical medicine.

The great developments which have taken place in the laboratory branches of medical research during the past thirty years, and which are reflected in the history of institutions such as the National Institute for Medical Research, are of course the result of development in branches of natural science other than those earlier recognized as being of direct importance to medicine, and of the growing realization of the closeness with which these other branches impinge upon medical and biological problems. It is within the period mentioned that biochemistry has emerged from its origin as a branch of physiology and has come to occupy its present status as an independent scientific discipline; it is also within this period, and particularly within the last few years of it, that the applications of various branches of physics to biological and medical research work have shown themselves to be of such outstanding importance.

It is notorious that the medical student often tends to doubt the importance and indeed the necessity for the instruction in the so-called basic sciences which he receives in the early part of his training. It remains difficult for the qualified medical man, unless he happens also to have been a serious student of some branch of science, to realize how closely dependent on scientific research work are the advances in practical medicine which are of immediate interest to him. It may therefore be worth while to reflect briefly on this question and to recall some examples of the way in which medicine is assisted by scientific work in the laboratory.

### Searching for New Chemotherapeutic Agents

Sometimes of course the application of science to medicine is so obvious and direct that it requires no emphasis or explanation. The production by an organic chemist of a useful new drug or of a new chemotherapeutic remedy is immediately recognized as a valuable contribution. But let it be remembered that the idea leading up to the synthesis of the new drug may well have been developed from the results of prolonged pharmacological research, and that this research in its turn was based on knowledge derived from experimental work in pure physiology. Let it be remembered also that advances in chemotherapy, at least in so far as synthetic compounds are concerned, depend on the progress of the science of organic chemistry itself. Moreover, although a new chemotherapeutic discovery may often seem to be a matter of luck, the process by which it has been arrived at is in all probability not so empirical as at first appears. Use is made more and more by chemists engaged in chemotherapeutic research of the great body of knowledge that has been built up in the past, and of the generalizations relating chemical constitution to biological and chemotherapeutic activity which emerge from this knowledge.

In this connexion we may go a step further and remind ourselves that biochemistry has also its contribution to make to chemotherapy and pharmacology. The conception of specific inhibition of biological reactions was first evolved and illustrated by Quastel and his co-workers by studies of the biochemical properties of simple enzyme systems. Applied by Woods and Fildes to the metabolic processes of micro-organisms, this idea has formed the basis of a reasonable theory of chemotherapeutic action. It offers a satisfactory explanation of the mode of action of the sulphonamides, and it points the way to a systematic method of searching for new chemotherapeutic agents. The full potentialities of the theory of specific inhibition have not yet been realized, there can be little doubt, however, that this biochemical discovery will prove to be one of the most important bases of further advance in chemotherapy and indeed in many other branches of medical research.

### Hormones, Vitamins, and Enzymes

In a similar way advances in endocrine therapy can be securely established only on a basis of biochemical investigation. Apart altogether from the obvious application of biochemical technique to the isolation of hormones in a state of purity, and the application of organic chemistry to the explanation of their chemical constitution and ultimately to their synthesis, theoretical biochemical considerations have led to many developments which would not otherwise have occurred. The discovery of the synthetic oestrogens, for example, which are of such therapeutic importance, had its origin in considerations of the relation of chemical structure to a certain type of biological action. The antithyroid drugs of the thiouracil type, which have revolutionized the medical treatment of hyperthyroidism, owe their discovery to the observation of a new type of goitrogenic action in experimental animals and to the skilful analysis of this observation on the basis of previously acquired physiological and biochemical knowledge.

Much the same considerations apply to work on vitamins. Whilst the existence of vitamins can be revealed and their general biological properties can be studied to a considerable extent by relatively simple methods, no real investigation of their mode of action in the body is possible until the pure substances are available, and they can only be made available by biochemical experiment. Moreover, the application of organic chemistry to the synthesis of vitamins, which has put them in the hands of physicians in large

amounts, has proved to be of therapeutic importance in several instances where intensive administration of a single vitamin has been found useful.

A further illustration of the direct importance to medical research of fundamental biochemical work is to be found in recent studies of isolated enzyme systems. These studies have revealed hitherto unknown biochemical reactions such as transmethylation, and in doing so have explained the real reason for the long-known fact that certain amino acids are essential, thus influencing dietetic theory and practice. They have produced much new knowledge of the chemical energetics of muscular contraction, on which must rest any satisfactory explanation of muscular fatigue. They are even approaching a demonstration of the interaction of hormones and enzymes which may lead not only to a great biological generalization but to much improved understanding of some types of metabolic disease.

In all these fields of biochemical work, therefore, investigations which are at first sight of purely academic interest prove not only to be essential to the proper and logical development of medical knowledge but are in reality quite closely connected with such development.

### Proteins and Viruses

To turn to quite a different subject, one of the major advances of recent years on the physical side of biochemistry has been the development of methods of study of the physical properties of proteins. Outstanding among these advances have been the application of the ultra-centrifuge of Svedberg to the determination of molecular size and molecular weight of proteins, and the use of the quantitative electrophoretic methods of Tiselius to define their electrochemical and other physical properties. Here again are two important pieces of scientific work which certainly do not appear to have much bearing on medicine. And yet it is largely on the information which has been gained by these techniques that the work of Cohn on the fractionation of blood proteins depends. The significance of this work for practical medicine needs no emphasis, one has only to think of its bearing on problems of blood transfusion and of the practical use that can be made of many of the separated proteins, such as the  $\gamma$ -globulin, which is a source of concentrated antibodies, and the fibrinogen, which, in the form of fibrin foam, provides a valuable haemostatic agent. Incidentally the very fact that the antibodies were to be looked for in a certain fraction of the serum globulins was discovered with the aid of the refined technique of electrophoresis.

The ultra-centrifuge has also found an important application in research work on viruses, its use has yielded valuable information in confirmation and extension of other physical methods, such as membrane filtration, concerning the size of different infective agents of this type.

Mention of viruses brings to mind another important development of physical technique—namely, the application of new optical methods and of the electron microscope to the study of microscopic and submicroscopic objects. Ultra-violet microscopy, which has been largely developed in direct connexion with medical research, offers a considerable extension to the range of the ordinary microscope, and recent research is making possible the use of ultra-violet microscopy for the examination of living material. Perhaps even more important for the study of living cells is the technique of phase contrast microscopy, which is now under active development, with its astonishing power of revealing fine structure. For the smallest objects of all we have the electron microscope with a resolving power of a different order from that of any optical method, the use of this instrument, employing the metal shadowing technique combined with special methods of preparation of the

material to be examined, such as supersonic dispersal, is indeed placing the morphology of viruses on a new plane

### Isotopes

The physical technique which is attracting most attention at the present time in respect of its applications to medical and biological research is of course the use of isotopes radioactive and stable, these isotopes form ideal indicators or tracers for following the course of biochemical reactions in the living body. In spite of the large amount of work on the subject which has been and is being published, the use of this technique in biology and medicine is really in its infancy. So far the tendency has been to use it for the obvious problems to which it gives an easy solution in the natural desire to reap as large a harvest of results as possible in the minimum time. Even so a considerable amount of valuable information has been acquired, there can be little doubt that, as the newness of the method wears off and more serious thought is given to its potentialities, it will be more and more employed, as it ought to be, for the solution of problems which can be attacked by no other method with any reasonable prospect of success.

### Other Branches

It may appear from what has been said so far that this article is heavily biased towards chemistry and physics, and that it is leading to the conclusion that all major advances in medical research in the laboratory are to be expected from the application of these two branches of science. Such a conclusion would of course be manifestly absurd, and no suggestion of the kind is intended. Great and important advances have also been made and continue to be made in the biological branches of laboratory research in medicine. We may think for instance of the development of the technique of tissue culture—a great discovery even if it has not yet yielded results of the importance that was first expected from it—and of new techniques such as the cultivation of viruses in developing eggs, which has been both of theoretical and practical importance.

Again, we may recall work in different branches of immunology, the prophylaxis of infective disease has been revolutionized by the laboratory research which led to the development of such immunizing agents as diphtheria and tetanus toxoids, the biological work which has been done in the laboratory on micro-organisms including viruses lies at the very root of problems of epidemiology, new knowledge of normal serological phenomena has been revealed, such as the existence of hitherto unrecognized blood groups, and in connexion particularly with the latter the importance of genetics in the natural history of disease has become more than ever manifest.

In pathology new knowledge has been obtained by experimental methods of the fundamental nature of the processes of inflammation as well as of the special pathology of many diseases. The scientific basis of pharmacology has been strengthened by the fundamental work which has been done on the mechanism of the transmission of nerve impulses. It would be possible to multiply instances of this kind, but it is surely unnecessary to say more in order to emphasize that the biological branches of medical research in the laboratory flourish and continue to play their full part.

Nevertheless there can be no doubt that the progress of biological work of all kinds is becoming more and more dependent on the techniques of chemistry and physics. Nor is it at all likely that this tendency, which is recognized by most biologists, will grow less. The experimental pathologist must not only have an understanding of the biochemical processes of normal tissues but he must be able himself to use, or to call in a collaborator to use, the appropriate biochemical technique to study the deviations

of these processes. The bacteriologist must be acquainted with the biochemical make-up and behaviour of the organisms which he studies. The virus research worker will not get far unless he has at his disposal all the modern physical and optical methods for the study of small objects. The immunologist needs the help of the protein chemist in the interpretation of his serological observations and in the practical application of his results to the production of useful therapeutic sera or prophylactic agents. The biochemist and the endocrinologist need the support, on the one hand, of the organic chemist for the purification and the synthesis of the compounds which are important to them and, on the other hand, of the physicist for techniques which will enable them to study the dynamics of processes as they actually occur in the living organism under normal and pathological conditions. In short no worker in any branch of laboratory medical research can now be independent. On the contrary, as the whole subject becomes more complex and as its ramifications increase he must increasingly lean on his colleagues in all the other branches.

### Some Pertinent Questions

If what has been said can be taken as giving a reasonable picture of medical research work in the laboratory as it is to-day, what are the implications? What are the probable developments? What opportunities does this type of work offer? Finally, what sort of men and women are needed to further its objects?

The first and fundamental point is that there is no place in a medical research laboratory for anyone who is not interested in scientific work for its own sake. It is true that the medical research worker cannot be as free from pre-occupation with the ultimate practical outcome of his efforts as can the worker in a university scientific laboratory, on the other hand, it is disastrous for him always to be thinking in terms of immediate applications. Once a general line of work has been selected the method of attack should be as free as possible, and there should be no hesitation in starting far back in what appears to be the chain of events leading to the phenomenon which requires explanation.

At the same time, while real interest in scientific work is the primary qualification for a medical research worker, there is very little limitation of the range of scientific activity within the field as a whole. Enough has already been said to make it clear that it is difficult to find a branch of scientific effort which cannot in some way contribute to the solution of medical problems.

This means that medical research offers the widest possible opportunities, and that these opportunities are open to medical and non-medical men alike. At the present time, for instance, the scientific staff of the National Institute for Medical Research is largely composed of men and women not qualified in medicine, and many non-medical workers are engaged in medical research in the universities. Ideally it would clearly be better for all medical research workers to have the background of a medical education. In practice this object cannot be achieved so long as it remains unusual for medically qualified men and women to devote sufficient time to the study of a scientific subject such as chemistry or physics to be able to carry out serious research work in it.

The system which has been adopted for this reason, and which has been shown by experience to work reasonably well, can remain satisfactory only so long as the chemists, physicists, and non-medical biologists who are engaged in medical research remain in close contact with medical men, and so long as they will use this contact to acquaint themselves with the important problems and to learn to understand and appreciate the mode of thought of their medical colleagues. It is at the same time most desirable for the

furtherance of medical research in the laboratory that more medical men should choose to devote themselves to this branch of their profession

It follows from what has been said that there is now little hope for success in medical research which is carried out in isolation. An almost essential condition is that such work should be done either in a university where good contacts are available with allied departments or in a research institute which is large enough to contain representatives of all the relevant branches of science. In this country this condition can now fortunately be fulfilled. The problems awaiting solution in the medical research laboratory are many and varied, and it is certain that no kind of work can bring greater intellectual satisfaction to those whose interest lies in science and who desire to help the advance of medicine.

## THE STRUCTURE AND FUNCTIONS OF THE MEDICAL RESEARCH COUNCIL

BY

F H K GREEN, MD, FRCP

*Assistant Secretary of the Council*

This account of the Medical Research Council—the British Government organization for promoting medical research—has been prepared, by request, for the guidance of those undergraduate and postgraduate students in medicine and kindred subjects who may wish to consider a research career, or at least to undertake a period of research as an incident in the course of some other form of professional activity. Before discussing constitutional and administrative details it may be helpful to summarize the opportunities offered by the Council to the would-be research worker by indicating, first, the range of its interests and activities and, secondly, the forms of support to the individual worker which it is prepared to give in suitable cases.

In the first place it should be emphasized that, although research into the nature and causes of disease and into improved methods for its prevention, diagnosis, and treatment naturally forms an extremely important part of the Council's programme, that programme is of very much wider scope. It deals also with the fundamental sciences of medicine—physiology, biochemistry, biophysics, genetics, and the like, with problems of nutrition and of the maintenance of general human well-being, mental as well as physical, and with the normal and abnormal physiological and psychological reactions of the human being to his work and environment. It may deal, indeed, with almost any question involving the human factor.

The chief forms of support to individual workers provided by the Council are (1) permanent or temporary staff appointments, (2) temporary research grants to independent investigators, (3) travelling and research fellowships, and (4) studentships for training in research methods. Each of these will be discussed under the appropriate heading below.

### History and Constitution

The coming into force of the National Health Service Act, 1946, provides a not unsuitable occasion to review the history and constitution of the Medical Research Council, for the Council, as at present constituted, is the functional successor of the former Medical Research Committee, which was itself a child of the National Health Insurance Act of 1911. That Committee was appointed in 1913 under the National Health Insurance Joint Commission to administer funds provided for research into tubercu-

losis and other diseases affecting the insured population. It had scarcely had time to embark upon its programme, however, before the outbreak of the 1914–18 war caused it to divert most of its attention and resources to the study of problems of urgent military importance. Co-operating closely with the Army Medical Service, it was able to promote an active programme of studies on such diverse subjects as wound shock and wound infection, cerebrospinal fever, amoebic dysentery, and schistosomiasis, which gave many results of permanent value. That the activities of the present Medical Research Council during the second world war were even more varied and many times more extensive may be gathered from the Council's Report for the years 1939–45, which was reviewed in the *British Medical Journal* of May 15, 1948 (p. 942).

With the passage of the Act of 1919 which set up the Ministry of Health there was a fundamental change in the administrative arrangements for the promotion of British government-aided medical research, one of the provisions of the Act being to transfer responsibility for continuing the work of the Medical Research Committee to a specially appointed Committee of the Privy Council. In 1920, accordingly, the former Medical Research Committee was reconstituted as the Medical Research Council under the statutory authority of the new Committee of Privy Council for Medical Research, the Council was granted a Royal Charter of incorporation, and the funds for its work were thereafter provided direct by the Treasury in the form of a grant-in-aid approved yearly by Parliament—an arrangement which has persisted since. The Committee of Privy Council for Medical Research consists of the Lord President, as Chairman, and of the Ministers in charge of the principal State departments concerned with questions of public health in the United Kingdom and in the Empire overseas, the Minister of Health is its Vice-Chairman and the Secretary of the Medical Research Council is *ex officio* its Secretary. The Lord President is the Minister responsible to Parliament for the Council's work.

It will be realized from what has been said that the Medical Research Council, although a Government organization financed from public funds, is not constitutionally a Government department. In fact as will be shown later, it is a nearly autonomous body predominantly of scientists, which enjoys full discretionary liberty in discharging its duties within wide terms of reference, its sphere of action in promoting medical research being unrestricted by rigid territorial or departmental limitations of function. The Council naturally maintains close touch with the several Government departments among which responsibility for public health is divided, and an important part of its programme consists in investigations of problems referred by the Ministry of Health and other departments for advice. It is able to collaborate freely on subjects of common interest with its sister research organizations—the Department of Scientific and Industrial Research and the Agricultural Research Council, both likewise under the Privy Council with the Lord President as their Minister. The Medical Research Council is also able to have direct relations with organizations in other countries having interests similar to its own—for instance, with the Rockefeller Foundation of New York, which has given much help to the Council's programme in many different ways over a long period of years. In administering the public funds entrusted to it the Council is not merely an advisory body but has full executive control.

### Membership

There are nowadays twelve members of the Medical Research Council—three lay and nine scientific. They are appointed by the Committee of Privy Council for Medical

Research, and they retire in turn at regular intervals. Of those appointed for general rather than scientific qualifications one at least must be a member of the House of Lords and one a member of the House of Commons. The nine scientific members are chosen to represent different branches of curative and preventive medicine and the fundamental sciences on which these are based, they are appointed by the Privy Council Committee after consultation with the President of the Royal Society, as representing independent scientific opinion in the country, and with the existing Council.

Scientific members who have served for the normal period of four years are not eligible for immediate reappointment, but the aim is always to ensure that the Council's scientific membership comprises a body of distinguished experts with first-hand experience of research in clinical medicine and surgery and in the more important of the basic sciences, as well as in some of the specialties of medicine. The Council appoints its own Secretary and its other administrative and scientific staff. The present Secretary is Sir Edward Mellanby, G B E, K C B, F R S.

#### Advisory Committees

The fact that the individual scientific members serve for only a limited period helps to give the Council flexibility of outlook and provides a useful variation in the range of technical interests directly represented by its members. Nevertheless, it is clearly impossible for the nine scientific members at any given time to possess detailed comprehensive knowledge of all the increasingly complex and specialized branches of medicine and allied subjects. To counter this difficulty, and to advise it in promoting research in particular aspects of medical science, the Council is assisted by a large number of expert technical committees which it appoints for the purpose. The terms of reference of these different committees cover a very wide range of topics, some of them are standing committees which assist the Council in the promotion of long-term inquiries over an extensive field, others are appointed on a short-term basis to organize research on a single problem or group of problems and are discharged on the completion of that task. Examples of the former are the Accessory Food Factors Committee and the Chemotherapy Committee and of the latter the two committees set up in 1946 to direct clinical trials of streptomycin in tuberculous and non-tuberculous conditions, respectively.

Two standing committees of special interest at present are the Committee on the Medical and Biological Aspects of Nuclear Physics and the Colonial Medical Research Committee, the latter appointed jointly by the Council and the Colonial Office to direct work on nutritional and other questions affecting the well-being of colonial peoples, including, of course, the study of tropical diseases. In promoting research on problems of industrial welfare and efficiency the Council is advised by its Industrial Health Research Board and by special committees on Occupational Medicine, Occupational Physiology, Occupational Psychology, Industrial Pulmonary Disease, etc. Members of the Council's advisory committees serve in a voluntary capacity, without payment. The Council meets about nine times a year, its committees as often as necessary.

#### Finance

The funds available for the work of the original Medical Research Committee in the year 1914 amounted to about £55,000, the Parliamentary grant-in-aid of the Medical Research Council for 1948-9 is £770,000, and additional provision from public funds for special non-recurrent expenditure brings the Council's budget for this year to over £1,000,000. At the outbreak of the 1939-45 war the

grant-in-aid was £195,000, and even by 1945-6 it had risen to only £295,000. The impressive increase in the size of the grant since then reflects not only the greatly increased cost of research but also a very wide extension of the Council's activities and commitments, for instance, the number of its research establishments was only sixteen in 1939, at present there are about forty. Important schemes of research now planned into some of the newer developments in radiotherapy for cancer—e.g., by the use of the synchrotron and cyclotron—must necessarily involve heavy non-recurrent expenditure on apparatus, for which Government authority has been obtained.

In augmentation of the public funds entrusted to it the Council is empowered by the terms of its Charter to accept charitable benefactions by gift or bequest for the support of medical research, some of these are used for the general programme, others are limited, by request of the donors, to work on specific subjects. The Council also from time to time receives grants from various public or semi-public bodies in aid of particular investigations. The cost of the Public Health Laboratory Service which the Council administers on behalf of the Ministry of Health (see below) is not a charge upon the research funds at its disposal but is provided separately.

#### Research Establishments

The Council's administrative headquarters are at 38, Old Queen Street, London, SW 1, and its central research laboratories comprise the National Institute for Medical Research, at present situated at Hampstead, and associated farm laboratories at Mill Hill, a special building where there is also nutritional research. The Institute at Hampstead—a former hospital, opened for its present purpose in 1920—has become inadequate for growing needs, and it is hoped within the next two years to transfer its work to a new and much more commodious building on the Council's land at Mill Hill, this was begun shortly before the 1939-45 war and is now being completed and equipped. Only laboratory research is done at the National Institute, the Council's programme of clinical investigations being carried out at other centres, as will be shown later. Nevertheless, though much of the research work at the Institute is necessarily of a fundamental nature, a substantial part of it has an immediate bearing on clinical problems, and numerous field studies in hospitals and elsewhere have been organized from the Institute. An instance is the new attack launched in 1946 on the aetiology of the common cold, which is being carried out in a special unit at the Harvard Hospital, Salisbury, maintained jointly by the Council and the Ministry of Health.

The research programme of the National Institute is a very wide one, divisible into the broad categories of physiology, pathology (including bacteriology, protistology, virus diseases, and immunology), pharmacology, chemotherapy, biochemistry, endocrinology, and physics in relation to biological research. Diseases recently under intensive study there have included influenza, malaria, and, during the recent war, the typhus fevers. A special responsibility of the Institute is to maintain standard preparations for the biological assay of certain drugs, hormones, vitamin preparations, and antitoxins, this is done both in fulfilment of statutory obligations of the Council in the United Kingdom and, in many instances, on behalf of the World Health Organization (formerly the Health Organization of the League of Nations). Sir Henry Dale, O M, G B E, F R S, was the first Director of the Institute, he was succeeded, on his retirement in 1942, by Dr C R Harington, F R S (now Sir Charles Harington).

It is obvious that in any comprehensive programme of medical research prominence must be given to the study

of problems of disease and injury as they are seen in patients—that is, to clinical investigations in hospital wards and out-patient departments. The Council has not established a special research hospital, deeming it preferable to take advantage of the available facilities and freer supply of clinical material at existing hospitals and the valuable opportunities to recruit and train new investigators which are provided by the day-to-day contact of research workers with undergraduate and postgraduate students at academic centres. In conformity with this policy it has for long maintained, wholly or in part, special units for clinical research at two London teaching hospitals and at the National Hospital for Nervous Diseases, Queen Square, London, W C 1. The oldest of these establishments is the Department for Clinical Research at University College Hospital, and it was here that the late Sir Thomas Lewis, F R S, carried out much of his famous work on diseases of the heart and blood vessels.

It has already been mentioned that the expansion of the Council's programme since the beginning of the recent war has led to a great increase in the number of its special research units. Many of these newer units have also been established primarily to study clinical problems, they include the Otological Research Unit at the National Hospital for Nervous Diseases, the Radiotherapeutic Research Unit at the Hammersmith Hospital, the Department for Research in Industrial Medicine at the London Hospital, the Industrial Medicine and Burns Research Units at the Birmingham Accident Hospital, the Pneumoconiosis Research Unit at Cardiff, the Department of Experimental Medicine at Cambridge, and the Clinical Chemotherapeutic and Clinical Endocrinology Research Units at Glasgow and Edinburgh, respectively. A Table listing the Council's chief existing research establishments other than the National Institute for Medical Research, at Hampstead, is given below.

The arrangement between the Council and the institution housing a particular research establishment varies from case to case, but the Council usually provides the medical and other scientific workers and the research expenses, the institution supplying accommodation and, in the case of the clinical units, the cost of feeding and nursing the patients. A statistical research unit has been an essential part of the Council's organization from the beginning of its work, the unit is housed in the Department of Medical Statistics at the London School of Hygiene and Tropical Medicine, the head of the Department, Professor A Bradford Hill, himself giving part-time service to the Council.

### Work Overseas

As an important ancillary to its programme within the United Kingdom the Council during the recent war dispatched a number of field research teams overseas to carry out intensive investigations of health problems affecting the armed Forces or the civilian populations of colonial territories. Before the war it had co-operated with other bodies in arranging a nutritional survey of Nyasaland, and it had awarded a number of fellowships to enable suitably qualified workers to undertake periods of field research on tropical diseases in various colonies. This type of collaboration with the Colonial Office has been greatly facilitated by the appointment of the joint Colonial Medical Research Committee, and by the setting up in 1944 of the Council's Human Nutrition Research Unit (see Table). Since then a number of members of the Unit and other workers for the Council have been sent to investigate health problems in overseas territories. An outstanding development of this kind has been the establishment in the Gambia of a Field Research Station with clinical facilities,

this, though supported from colonial development funds, is run in direct association with the Human Nutrition Research Unit in London, both being directed by Professor B S Platt, of the Council's staff.

Another overseas activity of the Council, also relating mainly to nutritional questions, was the formation of a temporary research unit at Wuppertal, as an annexe to the Department of Experimental Medicine at Cambridge under Professor R A McCance, its primary object was to study the effects and treatment of post-war malnutrition in the German population. A research mission of a different kind has been that sent by the Council to Cairo, by arrangement with the Egyptian Government, to investigate problems of schistosomiasis in areas where the disease is endemic.

### Research Staff

At the National Institute for Medical Research, at all the research centres listed in the Table, and at many others the Council employs a whole-time scientific staff, appointed on either a permanent or a temporary basis. There are at present about 300 members of the scientific staff, exclusive of technical assistants. Pensions for staff members on retirement are provided by insurance policies under the Federated Superannuation System for Universities.

In addition to those working in the Council's own research units, some members of the staff are attached to hospitals, university departments, or other independent research centres. Among the fields of study of these "external" members of the staff are problems of disease in children, nutrition, clinical bacteriology, tuberculosis, chemotherapy, and the biological effects of radiation.

### Research Grants

Although the greater part of the funds at the Council's disposal is devoted to the support of research by its own staff, an important fraction has always been expended annually in the form of temporary grants made in aid of approved researches by entirely independent investigators at universities, hospitals, and other institutions throughout the United Kingdom and, on occasion, overseas. These grants may be made variously for the personal support of the investigator on a whole-time or part-time footing, for the provision of scientific or technical assistance to senior investigators, or for research expenses. Grants made by the Council are usually awarded on an annual basis, and those made to workers for their personal support are not ordinarily renewable over a longer total period than three years. Where an application for a research grant comes within the field of interest of one of the Council's many expert committees the Council has the advice of the committee in considering it.

### Studentships and Fellowships

Reference has been made above to the advantages, from the point of view of the recruitment and training of new research workers in medical science, which are gained by the siting of most of the Council's clinical and other research establishments in teaching centres. As a further aid to recruitment the Council awards studentships for training in research methods to young graduates of special promise who are recommended for the purpose by the heads of the departments in which the training would be given. These studentships are tenable for a period of one year in the first instance, and are renewable up to a maximum of three years in all, subject to favourable reports from the supervisors of the studies, one of their chief objects is to make it possible for young men and women who otherwise might be prevented by economic factors from contemplating a research career to display their fitness for that type of work.

Apart from these training studentships, which are tenable in the United Kingdom, the Council awards certain travelling fellowships to enable suitably qualified British workers to undertake periods of study and research at centres abroad. It has for long acted as the agent in Great Britain of the Rockefeller Foundation of New York by awarding the travelling medical fellowships for British

latest of these Reports to be issued was that for 1938-9, but the series has been resumed with a six-year Report reviewing the Council's many activities during the war period, which was published a few months ago. Best known among the Council's several other series of publications are the green-covered *Special Reports*, of which more than 260 have been issued, on a diversity of medical subjects. Others

Table showing Principal Research Establishments of the Medical Research Council other than the National Institute for Medical Research (July 1948)

Subject	Establishment	Place	Present Director of Unit or Department or Head of Research Group
General medicine	Department of Clinical Research Clinical Research Unit	University College Hospital, London Guy's Hospital London	E E Pochin MD FRCP (post endowed by Rockefeller Foundation) R T Grant, OBE, MD MCRP FRS
Medicine (including nutritional and paediatric studies)	Department of Experimental Medicine	Cambridge University (with temporary field research unit at Wuppertal Germany)	Prof R A McCance, PhD MD FRCP FRS
Diseases of the nervous system	Neurological Research Unit	National Hospital Queen Square London	E A Carmichael CBE MB FRCP
Problems of ear disease and deafness	Otological Research Unit	National Hospital Queen Square, London	C S Hallpike, MB FRCP FRCS
Problems of vision	Vision Research Unit	Central London Ophthalmic Institute Judd Street WC1	H Hartridge MD FRS
Treatment of cancer	Radiotherapeutic Research Unit	Hammersmith Hospital London	Miss C A P Wood MRCP DMRE (half time)
Industrial diseases and poisoning	Department for Research in Industrial Medicine	London Hospital	Donald Hunter, MD FRCP (part-time)
Industrial health hazards including injuries and skin diseases	Industrial Medicine Research Unit	Birmingham Accident Hospital	J R Squire, MB, MRCP
Treatment of burns	Burns Research Unit	Birmingham Accident Hospital	" " "
Industrial pulmonary disease	Pneumoconiosis Research Unit	Llandough Hospital and other centres, Cardiff	C M Fletcher, MD, FRCP
Actions of drugs in man	Clinical Chemotherapeutic Research Unit	Glasgow University and Killearn Hospital	J Reid MD MRCP (part time)
Clinical aspects of endocrinology	Clinical Endocrinology Research Unit	Edinburgh University and Royal Infirmary	(At present directed by a Committee)
Nutrition	Nutrition Building Human Nutrition Research Unit	Mill Hill London National Hospital Queen Square London and London School of Hygiene and Tropical Medicine (with associated establishment in the Gambia)	Sir Edward Mellanby GBE KCB MD, ScD FRCP FRS Prof B S Platt, CMG, MB PhD
Nutrition (vitamin studies) (mainly vitamin studies)	Group for Research on Nutrition	Lister Institute of Preventive Medicine London	S S Zilva DSc, PhD FRIC
Dental disease	Dunn Nutritional Laboratory Dental Research Unit	Cambridge University King's College Hospital London	L J Harris ScD PhD FRIC J D King PhD LDS
Bacterial chemistry	Bacterial Chemistry Research Unit	Lister Institute of Preventive Medicine London	Sir Paul Fildes OBE MB FRS
	Group for Research in Chemical Microbiology	School of Biochemistry Cambridge University	Miss M Stephenson ScD, FRS
Cell metabolism	Cell Metabolism Research Unit	Sheffield University	Prof H A Krebs MD FRS (part time)
Problems of blood grouping	Blood Group Research Unit	Lister Institute of Preventive Medicine London	R R Race PhD MRCS
Preparation of blood derivatives	Blood Products Research Unit	Lister Institute of Preventive Medicine London	A N Drury CBE MD FRS (Hon Director)
Problems of transfusion	Blood Transfusion Research Unit	Postgraduate Medical School of London	P L Mollison MD MRCP
Chemotherapy of malaria	Group for Research in Chemotherapy	Molteno Institute Cambridge University	Miss A Bishop, ScD
Toxicology (with special reference to industry)	Toxicology Research Unit	Chemical Defence Experimental Station Porton	J M Barnes MB
Electromedical studies	Electromedical Research Unit	Ministry of Pensions Hospital Stoke Mandeville Bucks	R B Bourdillon CBE, MC, AFC, DM
Biophysics	Biophysics Research Unit	King's College London	Prof J T Randall DSc FRS (Hon Director)
Medical problems of nuclear physics (including research on health hazards)	Radioisotological Research Unit	Atomic Energy Research Establishment Harwell	J F Loutit DM MRCP
Molecular structure of biological systems	Unit for Research on the Molecular Structure of Biological Systems	Cavendish Laboratory, Cambridge University	M F Perutz PhD
Environmental physiology	Groups for Research in Industrial Physiology Research Unit on Climate and Working Efficiency	London School of Hygiene and Tropical Medicine Oxford University	(1) T Bedford DSc PhD (2) H C Weston FIES Prof W E Le Gros Clark DSc FRCS FRS (Hon Director)
Occupational psychology	Applied Psychology Research Unit	Cambridge University	Prof Sir Frederic Bartlett CBE, MA, FRS (Hon Director)
Psychological and other human problems of the building industry	Group for Research in Industrial Psychology	Manchester and elsewhere	S Wyatt DSc
Occupational psychiatry	Group for Research on the Building Industry Occupational Psychiatry Research Unit	Birkbeck College London Institute of Psychiatry Maudsley Hospital London	Prof C A Mace MA DLitt (Hon Director) Prof Aubrey J Lewis, MD FRCP (Hon Director)
Medical statistics	Statistical Research Unit	London School of Hygiene and Tropical Medicine	Prof A Bradford Hill, DSc, PhD (part time)
Social medicine	Social Medicine Research Unit	Central Middlesex County Hospital	J N Morris MRCP DPH DCH

workers generously provided by that body, and it has its own series of travelling and research fellowships in tuberculosis financed from a special benefaction in memory of Dorothy Temple Cross.

### Publications

Before the war the Council had to submit to Parliament an *Annual Report* on its work, which was published, the

deserving special mention are the white *Memoranda* started in 1940 as *War Memoranda*, which are used to record the results of certain *ad hoc* investigations or to give up-to-date advice on practical problems of medicine based on the latest results of research. All the Council's own publications are printed and sold by His Majesty's Stationery Office. The results of the great majority of the investigations supported by the Council are, however, reported direct by the

workers concerned in papers contributed on their own initiative to medical and other scientific journals

### The Public Health Laboratory Service

Reference has already been made to the Public Health Laboratory Service, organized and administered by the Council for the Ministry of Health since 1939. An account of the history of the Service and of its work to date was given by Dr G S Wilson, the Director, in his Milroy Lectures published in the *British Medical Journal* of April 3 and 10, 1948 (pp 627 and 677). The original object of the Service was to augment the existing public health resources of the country in combating epidemics of infectious disease such as were likely to arise from the abnormal conditions of war, and to keep a constant watch for any suspected instance of "bacterial sabotage". While the Service did not, in the event, have any example of "bacterial sabotage" to contend with, it proved so notably successful in elucidating and restricting outbreaks of infectious disease and bacterial food-poisoning during the war that it has been extended since as the framework of an organization for carrying out nation-wide investigations of problems of public health and epidemiology. At the request of the Government the Council accordingly agreed to administer the peacetime Public Health Laboratory Service on behalf of the Ministry for an initial period of five years. Statutory authority for the Service is provided in the National Health Service Act of 1946.

### Discussion

It is often asked is enough money provided in this country for the needs of medical research? It would be both unwise and untruthful to answer that question in the affirmative, for it is certain that additional funds could always be effectively used to assist research on important health problems to which new clues may have been provided by recent discoveries and for which suitably trained investigators with good ideas and good facilities are available. On the other hand it would be wrong to suggest that the present Government and its predecessors have failed to meet the requests of the Medical Research Council for increased funds for the support even of very costly new work which the Council believes to be necessary and promising.

It is important to remember, moreover, that the grants-in-aid provided by Government for the work of the Medical Research Council comprise only part of the financial support available in the United Kingdom for the encouragement of medical research; there are, in addition, the very substantial resources of the universities and hospitals and of various independent foundations and institutions, of the latter the Nuffield Foundation, the Wellcome Foundation, the British Empire Cancer Campaign, and the Imperial Cancer Research Fund are four examples among many of different kinds. The promotion of medical research in Britain, therefore, is not a monopoly, and both State and private enterprise contribute largely to it. The Council by its constitution is able to collaborate at will with any other official or private body having similar objectives, and a not unimportant part of its function is to decide whether a given investigation proposed to it would be better supported by itself or by some other organization with a view to avoiding undesirable duplication of effort.

The popular belief that a solution to even the toughest disease problem could probably be obtained at short notice by suddenly diverting to it huge sums of money and large numbers of investigators at a time when its prevalence gives it prominence in the newspapers unfortunately has little foundation in experience. This million-pound-in-the-slot-machine principle very rarely applies in medical science.

Time and again it has happened, instead, that control of a particular disease has been gained not by the method of intensive direct attack but as an unexpected result of patient fundamental advances on a much broader front and often involving an entirely different research discipline. Consider, for example, the recent studies of antibiotics, which have made possible the successful treatment of a large number of infections that had stubbornly resisted direct attack upon themselves as single diseases. It is for this reason that benefactions for medical research are often more effective when they are available for use in any part of the medical field which expert opinion deems ripe for exploitation than when they are rigidly dedicated to research on one subject, though cancer research and tuberculosis research, with their manifold problems, are obvious exceptions to the generalization.

Experience has shown that once a really hopeful new approach to a problem has been opened, and the right men or women with the right ideas are available to follow it up, the necessary money to support their activities will generally be forthcoming either from public or private sources. It is the need to find a new approach rather than just to spend more money which too often limits the speed of progress.

In an article published elsewhere<sup>1</sup> I discuss some of the reasons why medical research must generally be opportunist and can rarely be subject to long-term "planning" save in very broad outline (as by the appointment of a research establishment under a suitable director who is given a wide mandate within which to develop the details of his programme). Sir Edward Mellanby made nearly the same point some years ago when he remarked that the policy of the Medical Research Council was "to have no policy but to find the right men and back them in every way possible". The setting up of the Council's research establishments has largely to be governed by this opportunist philosophy—it is a question not only of realizing the kinds of problem urgently needing to be solved but also of finding men or women with the right sort of outlook, imagination, and experience, and of choosing centres with the best available facilities for their studies. Not infrequently the proposal to set up a new establishment has been put up to the Council by the investigator who subsequently has been made director of the unit concerned, though in other cases the Council has taken the initiative in starting a unit under a director considered to be suitable.

Large as is the number of the Council's research establishments at present, a glance at the Table will suffice to show that they do not as yet by any means cover the whole vast field of medical science. More units are being set up as opportunity offers, and the number of members of the Council's research staff increases each year. To meet the growing needs of the future there will be a call for more and more trained investigators in medicine and the allied sciences, and I have tried to indicate the range of opportunities which the Medical Research Council offers for such training to persons with a bent for discovery. The remarkable recent advances in so many different parts of the field have made the prospects for medical research more hopeful now than at any previous time: the demand for new recruits to the skilled army of investigators is correspondingly great.

<sup>1</sup>*Brit med Bull* 1948, 5, 352

The average annual production of quinine in India in the last three years was about 85,000 lb per year. Approximately 145,000 lb of quinine were imported into India during the last two years. There is at present a central stock of about 120,000 lb of quinine and the question of maintaining an adequate reserve is being borne in mind. The existing cinchona plantations in India are owned mainly by the Governments of West Bengal and Madras, and they are making every effort to maintain and increase production.

## THE STATISTICIAN AND MEDICAL RESEARCH

BY

MAJOR GREENWOOD, DSc, FRCP, FRS

*Professor Emeritus of Epidemiology and Vital Statistics in the University of London*

Statistics is—or are—an old science (or art), but Francis Galton, Karl Pearson, and W F R Weldon discovered a new application of statistical method at the end of the nineteenth century, and in 1902 the biometricians, as they were called, established a journal of their own, *Biometrika*, now in its 35th volume. The first volume of *Biometrika* contains a paper of medical interest—on the influence of previous vaccination in cases of smallpox—and others followed. For some years, however, the influence of the new race of statisticians on the logical procedures of either pathologists or clinicians was small and largely confined to destructive criticism. Biometrician A B—the actual letters were usually K P—would fall upon a paper by Dr C D and show that Dr C D's conclusion that treatment X gave better results than treatment Y did not follow from his data, that there was no significant (then and now a terribly overworked word) difference between the means of his two series. Even when, as sometimes happened, the difference was significant, A B would argue that other differences between the two series than the method of treatment might account for the result.

At first both laboratory workers and clinicians simply ignored the biometricians or called them mere mathematicians, often thought by clinicians and some biologists, like Almroth Wright, to be an inferior race of mankind. As J J Thomson once said, if ignorance of mathematics is a virtue it is surely the easiest of virtues. However, the tide turned, in 1910 the Lister Institute appointed a medical statistician and the Medical Research Committee (now Council) appointed another in 1914. Many statisticians now well known would acknowledge how much they owe to the friendship and encouragement of Sir Charles Martin or Sir Walter Fletcher which brought them through times of depression and frustration.

The widespread activities of the Medical Research Council and of an associated research committee, now the Industrial Health Research Board, led to increasing utilization of statistical methods, even in clinical research. In 1921 a statistical research committee was formed to take part in the planning and control of industrial-medical inquiries. Four years later this committee's terms of reference were extended and it became the statistical committee of the Medical Research Council itself. In the succeeding 14 years this committee had a large part in bringing statistical methods to bear upon laboratory researches as well as upon those field or factory inquiries which admittedly involved statistical analysis.

Contemporaneously, new statistical methods were used in non-medical laboratory and field biology. Progress in this way in agricultural research was particularly great, because one of the most gifted of contemporary statisticians, Professor R A Fisher, was for several years head of the statistical department of the Rothamsted Experimental Station. His epoch-making additions to statistical technique, applicable far beyond the bounds of soil research, were naturally first used in agricultural trials.

Now the biometricians have triumphed, indeed, some people may be reminded of Macaulay's rhetoric, that the whigs endured everything that O'Connell should not "be less than a British subject. We never will suffer him to be more."

### Demand for Statisticians

One may say, broadly, that the demand for statisticians has increased for two reasons. The first is that statistical methods have become far more exact and searching—i.e., capable of reaching results in fields which even so recently as 50 years ago seemed closed to them. The next is that experiments are expensive in money and time, we want results as cheaply as possible and as quickly as possible. It is therefore important to squeeze the last drop of information out of an experiment—i.e., to plan it properly and to analyse the data in the most efficient way. Suppose the experiment is a clinical one, that we desire to test the values of two treatments—A and B. I think, before Professor Fisher taught us better, that we should have looked at it in the following way. If we had available, say, 120 patients we should give A to 40, B to 40, and leave another 40 untreated.

Our 120 patients are not test-tubes, they differ in many ways, some of these differences may be relevant to the success of treatment, hence one must have a technique for the assignment of patients to each of the three groups which does not weight one group unfairly with persons likely to respond more (or less) favourably than others to treatment. But a statistician would not now recommend three groups of 40, unless remedies A and B were known to be incompatible. If, for example, the treatments were two different techniques for removing a new growth, clearly to give a group of patients both treatments is nonsensical. But often A and B can be combined, if therefore we had four sets of three: (1) AB, (2) A, (3) B, (4) neither, and assigned 30 patients to each, then not only should we be able to test whether the combination of A with B were better than either, which the "pure" experiment did not permit, but we have lost nothing in stringency of comparison of single treatments, for we can not only compare A against the "pure" controls but AB against B, if we wish to assess the value of A alone. This is a simple example of the economy of factorial design, and illustrates the fallacy of isolating factors, a doctrine which, as Professor R A Fisher remarked, "seems to be more nearly related to expositions of elementary physical theory than to laboratory practice in any branch of research."

### The New Method

An example of the power of statistical methods in medical research is the assaying of drugs by biological tests. Up to comparatively recent times laboratory workers were apt to look on mice or guinea-pigs just as test-tubes of different sizes and ages. I think the first worker in England to allow statistically for the fact that, just as mice individually vary in weight, appetite, and temper, they vary in response to doses of toxins or drugs, was J W Trevan, who published an important paper in 1927. In 1933 J H Gaddum's Report to the Medical Research Council extended the new method, and between 1937 and 1943 J O Irwin, of the Medical Research Council's statistical staff, published several valuable papers. In America, from 1934 onwards, C I Bliss and his colleagues did much research into the theory and practice of the method.

D J Finney's recent book (*Probit Analysis*, Cambridge University Press, 1947) gives a clear account of this new and valuable technique. The fundamental idea is simple enough. We are interested in a drug which can be tested only by administering doses of it to samples of mice and noting how many die at each dosage. Common sense dictates the drawing of a graph of the percentages which die at each dosage plotted as ordinates against the dose, or some function of the dose, as abscissa. But we must take account of the variability of response and remember

that even if we use equal numbers of mice at each dosage the points on the graph are not equally well determined, because, for statistical reasons, the precision of the ordinate for 50% fatalities will be greater than for 10% or 90%. Trevan noted that taking for abscissae the logarithms of the doses gave better results than using the actual doses, and a further transformation reduced the problem to the fitting of a straight line, now, very efficient routine methods of assay are available. But to reach this has involved a good deal of mathematical-statistical analysis.

Lastly, statistical methods play an important part in applied psychology. The pioneer was Charles Spearman, who concluded that scores in intellectual tests—for instance, examination marks in French or chemistry—could be expressed in terms of two “factors”—a general factor measuring something common to all cognitive activities and a special factor peculiar to each activity. Later research has shown the problem to be more complex than it first seemed to be, but psychological testing has grown and extended from the cognitive to the conative aspects of the mind and therefore interests psychiatrists and medical psychologists as well as schoolmasters and Civil Service examiners. Sir Cyril Burt's treatise, *The Factors of the Mind* (University of London Press, Ltd, London, 1940), gives a critical review of what is now called “factor-analysis”. Here again the construction of an adequate arithmetical routine involved a good deal of difficult mathematical analysis.

I have said nothing of the importance of the simple statistical methods, already understood well enough 50 years ago, in clinical medicine. Professor J. A. Ryle in his recent book (see *Changing Disciplines*, particularly p. 104 *et seq.*, Oxford Medical Publications, 1948) has spoken of this with a clinical authority I lack.

### BMA Committee's Report

Perhaps the reader is satisfied of the importance of statistical methods in all medical research, and he is sure to know that in the present undergraduate medical curriculum statistics, like liturgy, civil engineering, or the use of the globes, has no place at all. Even from the professional point of view this is a pity, my quotation from Macaulay's speech was not made at random. The medically trained person, whether laboratory worker or clinician, can no longer afford to despise the statistician, who for many years to come will *not* be medically qualified. He must accept him as a colleague, and unless the “doctor” does have some knowledge of the elements of statistical method the colleague will become, in the eyes of the world—which is becoming statistical-minded—not the colleague but the leader. Yet, down to the publication of the BMA Curriculum Committee's report on *The Training of a Doctor* (Butterworth's Medical Publications, 1948), no authoritative body has faced the position.

This report differs from those published by the Stationery Office during the war on educational problems, medical or general, in two respects, it is written in the English language, not in jargon, and can be read with pleasure because it develops a plan logically, and artistically. The committee thinks that statistical method should have a place in the first year of medical study because statistical ideas have their part in shaping current views of the fundamental sciences—namely, physics, biology, and chemistry—it recommends a course of 10 lectures, with practical work, and sets out a very reasonable syllabus. The whole of the committee's remarks (paras 86–91 on pp. 28–9) seem to me excellent. If I criticize the proposal it is not from lack of sympathy with the enlightened spirit which inspired it. A

class of first-year medical students will consist of young men and women who for the most part have learned *and remembered* little more mathematics than what is covered by the ordinary school-leaving certificate, indeed, if some medical faculty boards have their way, and medical students are not required to take mathematics even up to this standard, the average mathematical level of the class may be even lower. It is quite true that the principles of statistical method can be taught, and efficiently taught, without any more technical knowledge of algebra than many of the class will have or could quickly acquire. But that requires more time and a far more efficient and experienced teacher than the instruction of pupils with a serious mathematical background.

I do not think formal lectures should bulk in the course of instruction. No doubt an introductory lecture might rouse the enthusiasm of the class, be good propaganda, if the teacher had the gift of persuasiveness, it might, however, be merely dull. I should say that the best way of teaching is informal, one should try to combine a demonstration with a practical class. The teacher might, for example, give a short talk, say 10 minutes, on the advantages and disadvantages of common averages, the mean, the median, and the mode, and how these are computed. The class should then follow the heuristic method of Mr. Squeers and at once work out examples for themselves. As every experienced speaker or teacher knows, “impromptu” speaking and “informal” teaching require much more preparation than a set speech or formal lecture. In our particular case, worked examples and instructions to students can be mimeographed and distributed, but the difficulties many intelligent people have with “sums” are infinite, and the teacher must have had a good deal of experience to be able to remove or alleviate the student's perplexities. I am a pure Cockney, and my experience as student and teacher is wholly confined to London. In London there are not now enough teachers of the necessary powers to go round the medical schools. This might not be an unmixed evil. Although a statistical laboratory is not so expensive to equip as a physiological laboratory, aids to computation, such as calculating machines, cost a good deal of money. To confine practical work in statistics to what can be done by brute force and a table of logarithms would be as wise (or as foolish) as to restrict experimental physiology to what could be done on oneself—or a fellow student—with one's wits and ten fingers. Two or three equipped departments might receive all the medical students in London in a regular rotation so that the classes were small.

But unless the committee can persuade members of the faculty board and of the boards of studies within the faculty of medicine that statistics is not an elegant extra but a fundamental discipline, not indeed demanding as much time as chemistry, physics, and biology, but still fundamental, its plan will not succeed. Nobody dislikes examinations more than I do, but unless “human nature” has changed a great deal in the last 50 years—perhaps it has—the average student will not take much trouble over subjects unremunerative in marks. I hope the committee will succeed, all its members are clinicians and, for sound psychological reasons, their opinions are weighty. I think I should find it as difficult to persuade the board of the faculty of medicine to take the committee's plan seriously as a cobbler would find it to persuade me to double my expenditure on boots.

---

During 1947, 60% of fatal accidents and 38% of all accidents on building work reported to the Factory Inspectorate were on jobs not governed by the existing regulations for the safety and welfare of the workers. The Minister of Labour has therefore made new regulations under the Factories Act, 1937, to cover such cases.

## RESEARCH IN GENERAL PRACTICE

BY

WILLIAM N PICKLES, MD, MRCP

MOH Aysgarth Rural District Council

"I shall never have smallpox I shall never have an ugly pockmarked face," said an eighteenth-century milkmaid, with a proper pride in her youthful beauty "I've had cowpox, and girls who have had cowpox cannot take smallpox." That remark, made to or overheard by Jenner, is possibly a suitable beginning for this paper, as it foreshadowed an early and outstanding piece of research in general practice Jenner at that time was apprentice to a country doctor at Sudbury, in Gloucestershire, and found that this was a well-established belief in the county

Osler, whose historical accuracy in this matter has never been questioned, has many interesting things to say about smallpox "For centuries it had been a popular belief among farmer-folk that cowpox protected against smallpox. The notorious Duchess of Cleveland, replying to some joker who suggested she would lose her occupation if she was disfigured with smallpox, said she was not afraid of the disease, as she had had a disease which protected her against smallpox. Jesty, a Dorsetshire farmer, had had cowpox, and in 1774 vaccinated successfully his wife and two children"

Jenner subsequently mentioned the subject to John Hunter, who in reply gave the famous advice "Do not think, but try, be patient, be accurate" In 1780 the idea was firmly fixed in Jenner's mind, but it was not until 1796 that he made his first experiment He extracted matter from the pustules on the hand of a dairy-maid, successfully inoculated a small boy, and six weeks later matter from a smallpox pustule produced no smallpox

Even to-day at rare intervals a country doctor sees these pustules on the hands of a milker I last saw a man with this condition five years ago He told me he had never been vaccinated "Well," I said, "that was not very wise of your parents, but you are well protected now"

Benjamin Waterhouse, of Harvard, with whom Jenner exchanged affectionate letters and presents but never met, carried on the work in the USA, and with a series of successful experiments was said to have fully justified the conclusion of the Board of Health—"cowpox is a complete security against the smallpox"

The impression one gains of Jenner is of a man who realized that well-founded traditions of the countryside are worthy of notice, and of his extreme patience "The picture is that of a likeable, clubbable fellow, who could sing a good song and turn a copy of verses, with a taste for natural history" (M Greenwood) He has been assailed with much criticism, and not least from Creighton, who could see no good in him, even to the extent of pouring scorn on his observations as a naturalist, his observations on the behaviour of the infant cuckoo in its foster-parents' nest being characterized as a "tissue of inconsistencies and absurdities"

Greenwood, from whose *Epidemics and Crowd Diseases* I have acquired these facts, says "A moving picture has been taken of a young cuckoo ejecting its foster-brother from the nest and photographs of young cuckoos conforming to Jenner's description of their structure have been exhibited at a meeting of a learned Society", so it would seem that in this instance Jenner was not the imaginative rascal of Creighton's showing A man who unhurriedly followed up a country belief and patiently waited to confirm it is worthy of our regard, and many will believe that

his labours were and still are the means of saving thousands of lives

## An Early Epidemiologist

When Jenner died in 1823 a boy of 12 was being brought up in the traditions of medical practice in the family home at North Tawton, Devon He was to achieve fame in his lifetime, and, like Jenner, became a Fellow of the Royal Society, but his views were described as peculiar, and he was almost completely forgotten until a very few years ago his memory was revived, mainly by Edwin Goodall

William Budd's *Typhoid Fever* is one of the treasures of the epidemiologist, and his cold reasoning is a pattern to all those who essay to study the natural history of disease He shows particularly the advantages of country practice in the study of these problems "How often have I seen in past days, in the single narrow chamber of the day labourer's cottage, the father in the coffin, the mother in the sick-bed in muttering delirium, and nothing to relieve the desolation of the children but the devotion of some poor neighbour who in too many cases paid the penalty of her kindness in becoming, herself, the victim of the same disorder"

William Budd was no armchair epidemiologist, as this passage shows, his contact with his patients was personal and vital and he himself had been a sufferer from this fever He points out his own peculiar advantages "In addition to the advantages enjoyed by country doctors generally, in the observation of such events, there were others peculiar to the position I then occupied Having been born and brought up in the village, I was personally acquainted with every inhabitant of it, and being, as a medical practitioner, in almost exclusive possession of the field, nearly everyone who fell ill, not only in the village itself but over a large area around it, came immediately under my care For tracing the part of personal intercourse in the propagation of disease, better outlook could not possibly be had" Thus step by step he shows us that typhoid fever, thought in his day to be due to vague insanitary influences, was unexplainable except by the conception of contagion from one patient, directly or indirectly, to another

But this is not all of William Budd, and, although at the time of writing the following he was a consulting physician in Bristol, one feels that it was his earlier experience in general practice which really inspired it

"The idea that phthisis is a self-propagated zymotic disease, and that all the leading phenomena of its distribution may be explained by supposing that it is disseminated through society by specific germs contained in the tuberculous matter cast off by persons already suffering from the disease, first came into my mind unbidden so to speak, while I was walking on the Observatory Hill at Clifton, in the second week of August, 1856 The close analogy between this disease and typhoid fever had often impressed itself upon me with great force while I was engaged in the study of the latter I now saw with a clearness which had never occurred to me before, that with exception of the qualifications necessary for its application to a chronic disease—for the most part of slow evolution and indefinite duration—the leading conclusion to which I had been led, respecting the propagation of the fever might be applied with the same strictness to phthisis also"

## A Great GP

I am choosing a trio of the greatest of our general practitioners to build up my story, and the next giant is a rugged Scot who was born in Scone in 1853

After James Mackenzie had become a partner in a practice already of high traditions in Burnley, he set out to make himself a better doctor, the idea of research never entering his head

'About 1883 or 1884' his biographer tells 'I resolved to begin a series of careful observations entirely for my own improvement, never dreaming of research, for I was under the prevalent belief that medical research could only be undertaken in a laboratory or, at least, in a hospital with all the appurtenances. I had recognized that when the patient had some physical sign and when disease had made considerable ravages in the body, a moderately accurate diagnosis could be made, but in the vast majority of patients there was no physical sign, or, if there was a physical sign, I was not sure of its relationship to the patient's ill-health.'

He goes on to show how he began by taking notes of all his patients and then decided to narrow it down to those whose signs, and above all symptoms, were connected with the heart, and that was where general practice came in there was continuity, and "he was waiting to see what would happen to men, women, and children who showed these symptoms," and he was able to wait.

It ill becomes me to criticize this great man whose life was as truly a success as a life could be, but I feel that he did make one mistake—that is, in leaving Burnley, and breaking this continuity—and that he himself realized this when he quietly withdrew himself from London to semi-retirement at St Andrews, where he regained something of the atmosphere of his general-practice days.

Every young doctor should read the life of this lovable man. It has been a source of inspiration to me, as it will be to hundreds of other general practitioners. It exasperated him to think that all the recognition that he received and all the honours that were heaped upon him were due to his *polygraph*—the very useful instrument he invented—and not to the principles underlying his work. In *The Beloved Physician* we learn most of what we want to know about research in general practice.

### A G P with a Hobby

There is one among the many GPs who have added to the sum of human knowledge whom I cannot pass over, and his work was not strictly medical. Many doctors have done outstanding research in fields other than medicine, and I myself have known at least two distinguished antiquarians whose medical work was of a very high standard in addition.

The man I have in mind was a capable general-practitioner-surgeon whose ability in this work was recognized by the Royal College of Surgeons by the award of the rare honour of its Fellowship as a member of over 20 years' standing. Muir Evans, of Beccles, in Suffolk, who died at the age of 80 in 1947, used to say that he gave nine-tenths of his life to his profession and the remaining tenth to his hobbies. His field biology was a collateral of his work as a doctor, and his researches, beginning with the poison glands of fish, were of a very high order. In a paper on the pituitary gland of the eel, published in this *Journal* (April 6, 1940), he traced the seasonal changes in this gland.

One feels that a man engaged in busy practice who could produce so much in one-tenth of his working day must have done much for his patients.

### A Word on Record-taking

Shortly those of us in general practice will receive a record envelope, similar to that we have become accustomed to for NHI patients. I cannot stress too strongly the benefit we shall all gain if notes on these are kept conscientiously and, let me add, briefly. Thoughtful records are at the root of all good clinical work.

Let these notes also be legible. Old-fashioned people consider careless illegible handwriting a form of bad manners, and notes written in this way are valueless and a

source of irritation often to those who write them. First of all a fine pen should be chosen and time taken over the procedure. The typewriter is a good get-out for the illegible writer, but I very much doubt whether it can be used in this instance, so I say to those whose education has not included calligraphy, buy a copybook and learn to write a neat legible hand.

### Research Through the New Health Service

I am sad that so little has been said lately on group practice in the new Health Service. In the opinion of many there was fresh hope for the efficiency of general practice in the suggestion that doctors should work not as detached individuals but in groups—and if any contemplation of research is present, work in groups is of the highest importance.

It is not easy to indicate particular lines of research, indeed, it is undesirable to interfere with individualism. Every man, or rather every group, should choose his or its own. The following is the sort of incident which would suggest an investigation to me.

Many years ago, in one of our villages, I saw a sad little procession approaching me. An old friend and a great village character was being brought home dead in a cart, surrounded by his sorrowing relations. He had died suddenly out in the fields. He had consulted me many times because he was the victim of an intolerable pain in one of his calves after quite a short walk. This disappeared quickly on resting (as he was bound to do), only to return on another attempt.

I was very young. I had heard of intermittent claudication (how much happier is Ryle's name for it—angina cruris), but this was the first time I had met it. This incident set me thinking. "Is it a true danger sign, ought I to have warned poor James's relatives? Are all people who suffer from this complaint candidates for being brought home dead in carts or, in other words, liable to sudden death, probably, as he was in the fields, after exertion?"

Such were the thoughts that came tumbling into my head that morning as I stood on the village green. If I understood rightly the nature of the complaint it seemed more than likely that such people would die suddenly. This, then, was my first example, and my later experience is not great, but the end has been nearly always the same. The last sufferer was a dear old lady who, dozing quietly on a Sunday afternoon, suddenly became aware that her cherished garden had been invaded by a flock of geese from the village. Jumping up in a rage to drive them out, she dropped down dead. This is the only instance I have known of angina cruris in a woman.

It is an important subject, and the pooled information of a number of GPs would answer such questions as I asked myself that tragic morning. A group of sound general practitioners in a northern city lately, I am told, made systematic observations on the different psychological types in their patients suffering from peptic ulcer, with remarkably consistent findings.

Dental caries has always been to me a reproach as well as a fascinating problem, and I should much like to see whether painting the teeth twice—once before and once after the second dentition—with a solution of sodium fluoride really does protect against decay as our American friends tell us. Let me suggest this as a problem for a Health Centre, where I hope the examination of school children will at some future date be conducted by the family doctor, the doctor who will attend the child if he is sick, and not by the efficient but impersonal official.

But the problems are legion, and I feel inclined to reverse the idea of Mackenzie's and to suggest that an attempt to add to medical knowledge by the investigation of particular problems would inevitably produce a better general practitioner and, incidentally, would not fail in its objective.

The point of view of the country doctor is largely epidemiological, and that in its widest sense. If he were to find a proportion of his young girl patients victims of enlargement of the thyroid gland it would be fitting of him to inquire into the local conditions and to attempt to find out if there were anything in these which might contribute to the knowledge of its causation. He might then suggest a more generous fish diet—fish is not a common article in the country diet—even if it came from the village shop in tins. He might suggest the use of iodized salt as a routine, or he might even persuade his local M.O.H. to add iodine to the water supply.

There are problems of heredity which are readily available—the hereditary nature of skin diseases such as psoriasis, of rheumatic heart disease, as well as more obvious hereditary diseases such as Huntington's chorea or Friedreich's ataxia, and conditions such as polydactyly. There are also many problems in the study of epidemic disease waiting to be solved.

Writers of textbooks on infectious disease are handicapped, and are too often bound to give approximations, say, in the length of incubation period and the duration of infectivity for want of definite information. Yet this information lies within the grasp of the country practitioner if he be interested and will give his mind to it.

In country places that short and only possible exposure which alone gives this accurate information can very often be traced in a way which is well-nigh an impossibility in a town, with the varied experience of the town dweller. Country doctors should all read William Budd's *Typhoid Fever* and realize in those pages how great are their opportunities and how much better and more interesting would be their work if the lead which lies close to hand were assiduously followed. Work of this sort in the field is a possibility in itself, but its value would be greatly enhanced should the practitioner form a close liaison with the director of a laboratory. This helpful co-operation is now possible, or will be possible to all in the future.

Lastly, there must be a bond between the general practitioner and the medical officer of health and the Health Services. May I plead with the M.O.H. to get to know all the general practitioners in his area and to be willing at all times to give them his help?

Research is not a matter of gusts of inspiration but the result of patient observation undertaken with no thought of self-advancement. "In the fields of observation chance favours only the mind which is prepared." So wrote Pasteur. May those of us in general practice see that our minds are thus prepared.

## MEDICAL EDUCATION IN THE UNITED STATES

BY

RAYMOND WHITEHEAD, D.Sc., M.D.

(From the Department of Pathology, University of Manchester)

From the British standpoint the study of American medical education is valuable chiefly because it throws into relief the characteristic features of our own system. Although they have much in common, the British and American systems of medical education each have many distinctive features. These are expressions of the different historical circumstances of the two nations, and the possibilities of directly transferring the methods of one country to the other are accordingly limited. Mutual influence is more likely to be fruitful, ideas and principles travel better than particular applications of them, and, if adopted, it is best that they should take forms suited to the national genius. It will be helpful first of all to describe the American institutions concerned in medical education.

### Colleges

The highest form of general education is given in colleges of liberal arts and sciences. These institutions have no British counterpart, they are neither schools nor universities but have features of both. Some colleges are independent, under a president, others form part of a university, when they are administered by a dean. There seems to be no essential difference between the independent and the university colleges. The primary purpose of a college is to give general education of an advanced type, but professional subjects such as engineering are sometimes taught, research work is not a normal function of a college even when it forms part of a university.

Students enter colleges as a rule at the age of 18 and follow a four-year course, receiving at its close the degree of Bachelor of Arts (A.B.) or Bachelor of Science (B.S.). The degree is obtained by accumulating a required number of credits. These are records of the satisfactory completion of a certain number of hours in a course, as shown by examinations conducted by the instructor who gives the course. Comprehensive examinations similar to those in British universities are unusual. The standard of the American college degree is probably about the same as that of a British pass degree. The difference between American college degrees and British university degrees with the same titles lies not so much in the standard as in the range of knowledge required, for American degrees this is usually wider and less directly vocational than that represented by a British B.A. or B.Sc.

### Universities

The typical American university consists of a college of the kind described above and a variable number of professional schools. The term faculty is used in two senses: first, in the abstract British sense of a main division of university work, particularly postgraduate work, and, secondly, to denote the staff ("the faculty" is exactly equivalent to "the teaching staff" in British usage). The college and each school are administered by deans, their powers are wide, resembling those of an English vice-chancellor, and the relation between a dean and the professors of his school is similar to that between the vice-chancellor and the senate of a modern English university. The chief officer of a university is the president, and the governing body a board of trustees—men of standing in

---

A Clean Food Association has recently been formed in Caernarvonshire. It will have as its primary objects the safeguarding of the people's health and raising the hygienic standards of food production and handling. Representatives and officers of all the local sanitary authorities and of the county council, together with elected representatives of food production and handling organizations in the county, will be members of the Association. All restaurants, cafés, milk bars etc. will be encouraged to attain and maintain a prescribed standard of cleanliness and hygiene in the preparation and handling of food and to each establishment attaining the standard will be given an authorized certificate for display. Educational talks and film displays will be arranged for food handlers, and scientific information will be distributed to all those concerned. According to Dr D. E. Parry Pritchard, the County Medical Officer, Caernarvonshire is the first county in England and Wales to direct combined and co-operative efforts in this direction.

business or the professions. Each school manages its own affairs but is responsible to a central administration.

Students reading for higher degrees are known as "graduate students." Such students work in any building (college or professional school) with the necessary facilities, but all are deemed to belong to the "graduate school" of the university irrespective of their field of work. Although it has no buildings, the graduate school has a dean. Not all graduate students are research students, most of them read for the degrees of Master of Arts (A.M.) or Master of Science (M.S.). Training in research methods is usually given to candidates who have matriculated for the degree of Doctor of Philosophy (Ph.D.).

The professional schools often require their students to be college graduates. Work in such a school for a number of years leads to a professional degree, that of bachelor, except in medicine and related fields such as dentistry, in which it is a doctorate, originally the initial medical degree was M.B., but this has virtually disappeared. Surgery and obstetrics are not recognized by special degrees.

The most important non-professional degree is the Ph.D. This is awarded by the graduate school for work in any field of knowledge (including medicine) and is normally held by those teachers in medical schools who are not medically qualified. The Ph.D. can be obtained by three years' work after graduation as a bachelor at a college, but often four years are spent on it. The course consists partly in research work (on which a thesis is required) and partly in study similar in nature to an honours course for British undergraduates. The final examination is of a high standard and includes a searching oral test. The D.Sc. degree is normally awarded only *honoris causa*.

Some universities are private, being financed (apart from fees) by income from endowments, by gifts from private persons, or by grants from foundations, others are State or municipal institutions. Both types—the private and non-private—are organized on the same lines, and it is doubtful whether they differ in quality.

College and university students may live where they please. Many institutions have halls of residence known as "dormitories." Fraternities, which are student clubs and in many cases wealthy corporations, also maintain club-houses where the members may reside. The fraternities are often national organizations, and a single fraternity may maintain a house at each of many colleges and universities. Some fraternities are professional, their houses being reserved for students preparing for a specified profession. The corresponding organizations for women are known as sororities.

### Medical Schools

Until the chaotic state of medical education in the United States was revealed in a report prepared by Mr. Abraham Flexner about forty years ago, many medical schools were notoriously inefficient. As a result of this report, about half the medical schools disappeared and standards were set up under the auspices of the American Medical Association and the Association of American Medical Colleges. The result is that the United States now possesses some of the best-designed and best-equipped medical schools in the world.

The first great American school, that of the Johns Hopkins University, Baltimore, was opened in 1893. The Johns Hopkins medical school is famous for many things, only three can be mentioned here. (1) it was the first American embodiment of the research spirit of nineteenth-century German medicine, (2) it set an example by requiring a high standard of general education in candidates for admission, and (3) it introduced, in 1914, the system of a

full-time teaching staff in the clinical branches of medicine, thus placing the whole of medicine on a university basis.

The full-time system is now an accepted principle of medical education in the United States and has recently become so familiar in this country that no description of it is necessary. It is, however, worth noting that, like the full-time clinicians, the full-time pathologists are primarily teachers and research workers rather than routinists. The routine pathology—necropsies and surgical histology—is done (under supervision) by young clinicians who also share in the teaching of students. This arrangement benefits all concerned: (1) the clinicians, who receive a valuable training in the correlation of signs and symptoms with structural changes, (2) the students, who are largely taught by men with up-to-date knowledge of the clinical branches of medicine, (3) the full-time pathologists, who have adequate time for research, and (4) the hospital staff, whose heavy demands can easily be met owing to the number of routinists available.

At the Johns Hopkins University the medical school and hospital occupy separate buildings, but modern opinion favours the union of school and hospital in a single building. For example, at Rochester, New York, where a medical school was opened in 1925, a single building houses the medical school, the university hospital, and the municipal hospital, which for all medical purposes form a single institution. The plan of a single building was adopted with the object of promoting the closest possible co-operation between all departments, clinical and non-clinical, in teaching and research. The plan has the further advantage that duplication of services is avoided—the whole institution is served by a single workshop, animal house, photographic department, and pathological laboratory.

American medical schools are inspected and graded by the American Medical Association, which indicates shortcomings privately to the schools concerned, the American Medical Association thus performs functions that in this country would be regarded as appropriate to an official body.

The Johns Hopkins medical school has in the course of time lost its unique distinction owing to the rise of other first-rate schools. How many schools may properly be so described is a matter of opinion, but there is general agreement among American medical teachers that about twelve schools now qualify.

### The Medical Curriculum

Pre-medical education is obtained in colleges. For prospective medical students the college course includes chemistry, physics, botany, zoology, English, and either French or German. In his final college year the student takes the scholastic aptitude test of the Association of American Medical Colleges. This is a test of (1) comprehension and retention of a previously unseen mass of facts, (2) visual memory, (3) memory for content of an anatomical diagram, (4) general information, (5) logical reasoning, (6) scientific vocabulary, and (7) understanding of printed material. The student's performance in this test, details of his standing in college, and reports from his science teachers are considered by the medical school and promising candidates are interviewed. On account of this careful selection most of the students admitted complete the course.

The medical course lasts four years, the first two being preclinical, the last two clinical. The subjects of study are substantially the same as in this country, but the systematic courses of instruction in pharmacology, pathology, and bacteriology are completed before clinical work is begun. Towards the end of the preclinical period

instruction in clinical methods is given. The clinical period is spent first in the wards, later in the out-patient departments. On completing his course the student receives as a rule the degree of M.D., which qualifies him for an internship (house appointment). The right to practise independently is obtained by passing one of the State examinations or the final of the National Board (roughly equivalent to the Conjoint Board). Many States require candidates for their examinations to have completed one year of internship.

### Methods of Teaching and Examining

The student's work is carefully planned and supervised. In most subjects there is one teacher to every three or four students. Each teacher forms an estimate of each student, taking into account character and personality as well as ability. These estimates may be expressed as marks—as many as half the possible marks in a professional subject may be reserved for teachers' estimates, only half being obtainable at the examination. For this reason examinations are less important than they are in this country.

One or more subjects are commonly studied intensively all day and every day until the ground has been covered, in this way anatomy may be finished in six months, histology in three. The study of clinical subjects is similarly concentrated, each major and minor subdivision receiving so many months or weeks according to its importance. Throughout his course the student may spend most of the day (8.30 a.m. to 10 p.m.) in the laboratories, lecture rooms, or wards and has less time for reading than the British student. One or two half-days a week throughout the course may be kept free for work of the student's own choice—research work or an optional course.

During the clinical period the student has access to patients at all hours of the day and night. The student is an indispensable member of a team—the normal work of the hospital could not be done without him.

The standard of knowledge attained varies with the subject. In anatomy it is not so high as in this country, probably owing to the relatively short time spent on it and the consequent necessity for high-speed dissection. In biochemistry, on the other hand, the standard is much higher, in physiology, pharmacology, pathology, and bacteriology it is about the same. In the clinical subjects the student has more responsibility for his patients and does more routine work than in this country, on the other hand his experience, especially of obstetrics and emergency work, is often narrower than the Englishman's. Venereology receives more attention and forensic medicine less. Medical history is taught in some schools, forming one of the optional courses.

Perhaps the most distinctive feature of American medical teaching is the clinical-pathological conference. This is a standard form of instruction that the student attends once a week throughout the clinical period. The details of procedure vary in different schools, but the general plan can be seen from the following example. The conference takes place in the post-mortem room and lasts exactly one hour (12 noon to 1 p.m.). It is attended by all the staff of the pathology department, the radiologists, many clinicians besides those directly concerned with the cases studied, and all students qualified to attend. Three or four cases are presented on unfixed material that has been kept in a refrigerator. The following topics are dealt with in the order named: (1) clinical history, (2) x-ray report and demonstration of films by a radiologist, (3) comments by clinicians of "honorary" status, (4) post-mortem findings by the pathologist who performed the necropsy, (5) comments by the professor of pathology, who then answers questions,

(6) formal description of the organs by the professor of pathology, (7) questions and general discussion. Criticism of the diagnosis and treatment is frank and free, and there is no respect of persons by either colleagues or students.

### Discussion

From the information given above it will be clear that the American system of medical education differs considerably from ours, and some of its main features will be briefly discussed.

The selection of medical students is a difficult problem and probably explains the introduction of the scholastic aptitude test. It should, however, be noted that this is only one of the various aids to prognosis, and that great importance is also attached to the interview.

The preclinical study of pharmacology, pathology, and bacteriology would not find favour with British teachers. An elementary knowledge of these subjects is necessary if the student is to profit by clinical instruction, the completion of the systematic courses in them before clinical work has begun is undesirable. This point may be illustrated with reference to pathology. The object of teaching pathology to medical students is to enable them to understand the changes in structure and function that occur in disease and so to interpret signs and symptoms accurately. The discussion of pathological phenomena that the student has not seen in patients is largely a waste of time, for this opinion there is ample evidence from the experience of dental students when they have been required to follow a pathology course designed for medical students. Under these conditions the dental students are often bewildered, and the pathological instruction conveys very little to them. The fact is, of course, that pathology and clinical medicine and surgery are not distinct subjects that can be profitably studied apart, but simply different approaches to a single problem—namely, the man who is ill. Ideally, pathological teaching should thus continue throughout the clinical period. In practice, however, this would mean overloading the final examination, and a sensible compromise is to hold the examination in pathology some time before the final in order to allow the student to concentrate on the clinical aspects of his work. If the intimate relation between pathology and clinical work be granted it follows that a pathology course for dental students should be specially designed, at least after the completion of the study of general pathology.

The high proportion of teachers to students in American schools makes it possible to give the students more individual attention than is practicable in this country and also puts at the student's disposal a wider range of interests and experience. The elaborate system of grading of the students by the teachers is probably a natural development made possible by the abundance of teachers.

The significance of examination results is not the same as in this country. The American student is judged on his knowledge, class work, and personality, the British student on his knowledge alone. A pass in a British examination means that the student has mastered the essentials of a subject, a pass in an American examination does not equally guarantee this, because a proportion of the marks may be awarded on grounds other than the demonstrated possession of knowledge.

The intensive system of teaching allows the student too little time for reading and rumination and denies him the relief of studying different subjects concurrently.

Clinical-pathological conferences are a valuable means of correlating clinical findings and pathological changes. They are valuable for students and even more so for clinicians and pathologists, who are thus regularly brought into

conference The conferences are most instructive when they relate to patients recently dead, since many of those attending will have seen the patient during life and will therefore have the problems of diagnosis and treatment vividly in mind, a conference on patients dead long ago is less instructive, despite the more complete documentation, including histological reports on material removed at necropsy Since the main object of a conference is the instruction of students, the cases should preferably illustrate the common diseases, and the conference should be conducted throughout with the student's limited experience in mind, difficult cases requiring specialized clinical or pathological knowledge would be best discussed at conferences for graduates only

### Summary

The institutions concerned in medical education in the United States are described and the education of the American medical student is described and compared with that of the British student

Medical education in America is conducted on the same general lines as in this country, and the subjects of study and their scope are substantially the same

The distinctive features of American teaching are (1) the sharp separation of non-clinical from clinical studies, (2) the high proportion of teachers to students, (3) the important place of the student in the hospital team, (4) the relative unimportance of examinations, (5) the intensive system of study, and (6) clinical-pathological conferences

One year of internship is a common prerequisite for independent practice

I am indebted for discussions to many medical teachers, British and American, and to British students who worked in American schools during the war I am grateful to Professor I L Kandel for expert advice on American education and to Professor S L Baker for reading the manuscript

## Nova et Vetera

### JOHN WILLIAMS AND THE EARLY HISTORY OF YELLOW FEVER

BY

G M FINDLAY, CBE, MD, FRCP

The early history of most diseases is lost in the mists of time This is not as a rule a matter of great importance, but in the case of yellow fever it would still be of considerable interest to know whether in historical times the infection had first passed from Africa to America or from America to Africa, or whether the evidence favours the view that the disease was present long before the coming of man, when Gondwanaland still included what is now South America and Africa If the yellow fever virus could colonize a new continent in the sixteenth or seventeenth century it might conceivably do so once again

One of the arguments which has always been used by those who favour the American origin of yellow fever has been that whereas the first recorded outbreak of the disease in the New World was in 1648 in Guadeloupe, Havana, and Yucatan (Du Tertre, 1667-71, López de Cogolludo, 1688), and almost certainly in 1647 in Barbados and St Christopher (Ligon, 1657, Scott, fl 1634-96, Winthrop, 1853), the first record of an outbreak in the Old World is not till 1778, when the Hessian, John Peter Schotte (1782), described yellow fever under the name of "synochus atrabiliosa" in St Louis de Senegal

An authentic record of yellow fever in Africa which considerably antedates Schotte has now been found This occurs in a pamphlet published by John Williams at Kingston, Jamaica The pamphlet is entitled "An Essay on the bilious or yellow fever of Jamaica" [Petet autem novum quoque consilium, non ab rebus latentibus (istae enim dubiae & incertae sunt) sed ab his, quae explorari possunt, id est, evidentibus Causis

A Corn Celsi Praef] Kingston Printed by William Daniell, Printer and Bookseller, at the New General Printing Office, the corner of Water Lane in King Street, near the Court House, 1750

This little work seems to have had only a limited circulation There is no copy in the British Museum, but one exists in the library of the University of Edinburgh and another in the Surgeon-General's Library in Washington\* The first edition was, however, reprinted in London in 1752 by T Waller, opposite Fetter Lane in Fleet Street, and was sold for the sum of two shillings Of this edition there are more examples, as for reasons which will be detailed it created some general interest Its significance, however, has been overlooked by those interested in the history of yellow fever The "Essay on the bilious or yellow fever" met with considerable criticism from Parker Bennet, a physician resident in Jamaica, who wrote 'An enquiry into the late Essay on the bilious fever' This inquiry stirred John Williams to a poetic flight in heroic couplets, after the manner of Mr Pope, in "An Epistle to the Honourable Charles Price, Esq," whereupon Bennet replied in 'A prose epistle to a poetic epistle writer' This in its turn was followed by "A letter to Doctor Bennet" from Williams with the motto 'The mouth of them that speak lies shall be stopped'—Psalms lxxii 11 This letter could not have been published until after Nov 27, 1750, and was the last written communication between John Williams and Parker Bennet, for on Dec 29 they came to blows which, in the words of the anonymous editor of the 1752 reprint, 'terminated in the death of both' Before retelling this curious incident it is proposed to discuss the reference to yellow fever on the West Coast of Africa

### Yellow Fever in West Africa

Williams describes very accurately the symptoms of yellow fever as he knew it in Jamaica He then goes on, "I do not apprehend this fever is what we call a local disorder, for I have seen it upon the coast of Africa, and am well informed that in the River Benue they have a bilious or yellow fever acuter than what it was here, at the time of the expedition to Carthage, the persons seized with this fever dying there in less than twenty-four hours This disorder is generally brought on by suddenly cooling the body and checking perspiration after hard exercise in the heat of the sun for when sailors go to cut wood for the ship's use they are obliged to row several leagues against a current and then jump into the water to carry the wood on shore"

John Williams, it appears, had been a surgeon on a Guinea man, that is to say, a slave ship plying from Guinea to the West Indies, for Bennet twits him with having gained most of his experience in treating African negroes on the coast of Guinea Bennet, it may be noted, was an M D of Edinburgh, while Williams, who is always referred to by Bennet as "Mr Williams," states that he had acquired his experience "like honest and careful Svidenham" and had "made himself acquainted with the diseases of the country never sacrificing his patient to any favourite hypothesis" That the assertion by Williams that he had seen yellow fever in Africa was not regarded as remarkable is seen from a statement by Bennet in his "Enquiry into the late Essay on the bilious fever" "We assure him," Bennet says, "that some of us have been in Africa, on board Guineamen, and in other islands of the West Indies as well as he, consequently we are equally entitled to write upon and cure the yellow fever Physic is a science not to be acquired by mere dint of natural parts"

There is no doubt that Williams actually described yellow fever According to him, "The distinguishing symptoms or diagnostics of this disorder are, besides what is common to fevers, great anxiety, heat and pain at the scrobiculum cordis, some degree of inflammation of the liver which frequently causes a jaundice, bilious vomiting or ejections, or both, some times an acute, sometimes a dense pain about the region of the liver, all manifest signs of inflammation Sometimes we find the right hypochondr tumified, frequently hard Many cannot bear pressure on the right side or to lie on the left From these symptoms to worse—strong and continued convulsions of the diaphragma, intercostal muscles and stomach, aeruginose

\*A microfilm of the first edition is now in the library of the British Medical Association

vomiting—then vomiting black adust blood, appearing like the grounds of coffee mixed with acrid unfinished bile, the juices of the stomach and pancreas both very sharp—bleeding from the emunctories or delirium or phrenzy general gangrene and death. These are indeed dreadful symptoms." This is by no means a poor description of yellow fever.

In many ways Williams was in advance of his times, for he distinguished quite clearly between yellow fever and the common bilious remittent. He notes, for instance, that the remittents described by Hippocrates were of a different kind from the yellow fever. "His bilious or yellow fevers were not so acute as ours, they terminating commonly in seven or nine days, sometimes in fourteen." In addition Williams seems to have recognized that he was dealing with something different from the common fever of Virginia. "In Jamaica a cooling regimen, solutive and diluting medicines succeed best and the disease soon arrives to its acme or state and consequently is soon determined. In Jamaica in this ardent fever I treat of, the strongest alexipharmics and sudorifics would bring on a delirium or phrenzy and destroy the patient. In Virginia we are to promote, at all events, the concoction of the febrile matter by the use of alexipharmics and sudorifics, although by these we translate that febrile matter to the brain and bring on a coma we must keep up the pulse until the crisis which generally happens on the seventh, ninth and sometimes the eleventh day. In Jamaica all we can do is little enough to suppress the fever. In Virginia nothing is so serviceable in the remissions as the Peruvian bark, or even in the height of the fever without regard to the exacerbations or remissions. In Jamaica the bark in all forms hath frequently been tried in the remissions but without success. Indeed it generally does much harm."

Williams was thus considerably in advance of Schotte, who still believed that the synochus atrabiliosa of Sencgal was merely a more malignant form of remittent fever. Well on into the nineteenth century it was customary to classify deaths as from bilious remittent fever and malignant bilious remittent fever, and even as late as 1874 the *British Medical Journal's* "Own Correspondent" on the Gold Coast had difficulty in distinguishing between yellow fever and malaria. "The yellow fever on merchant ships," he says, "has been contracted in the Bights especially at Bonny where they lie for several days while steam tenders collect oil from the neighbouring rivers. The disease is really more a severe form of malarial remittent than true yellow fever but not a whit the less deadly."

Williams also had a fair idea of the pathology of yellow fever. "In subjects who died of this disorder the liver was increased in bulk and greatly inflamed on the concave parts large black spots appeared, which were mortified parts of that viscus. The gall bladder was frequently empty. The mesenteric veins in the intestines which all deliver their blood into one large trunk which constitutes the vena-porta were vastly turgid with blood and the whole intestinal tube appeared livid, the inner coat being covered with a gangrenous bloody slough, which when washed off, the mesenteric vessels appeared blackish and turgid with blood. If an inflammation happens in the liver an ardent fever with a jaundice must succeed." Many later writers entirely ignored the pathological condition of the liver and concentrated on the inflamed condition of the intestinal tube.

Williams's views on prognosis also appear quite modern.

If a jaundice comes on soon, it is bad, if with livid spots fatal. If the vomitings are incessant grow darker and the hiccup comes on, it is generally fatal. If the face is greatly flushed and the vessels on the tunica adnata turgid with blood with a concomitant phrenzy you might expect the patient's death in a very little time, especially if the skin is dry. The blood is dissolved to such a degree sometimes as to force its way thro the skin itself, or burst out from some small twig of an artery on the surface and this haemorrhage is so violent, it cannot easily be restrained. This was the case of Doctor Dwyer and of several others."

It was by his remarks on treatment apparently that Williams stirred the wrath of Dr Parker Bennet and by his assumption that newcomers who had learnt only the theory of medicine could not possibly know how best to treat yellow fever. These gentlemen argue Williams says, "that by some occult venom contagion miasma or Je ne sais quoi the texture of the blood

is broke whence it is turned into a vapid and putrid mass, runs off through the glands therefore the blood is in the same state as in pestilential fevers and give sudorifics and what are called alexipharmics, as in the pestis, insisting the most likely means to save the patients is to keep open the skin. How pernicious must the theriacal draughts, given by some in the beginning of this fever, be. How destructive cardiacs, volatiles and all spirituous medicines. If they will have alexipharmics why do they not give fresh lime juice which is perhaps the greatest in the world? Lime juice so powerfully prevents the dissolution and fluxility of the juices that it is almost impossible to raise a salivation by mercury, if the patient suck limes plentifully at the same time. These medicines, commonly called alexipharmics, hurry on the inflammation to a gangrene. Lenient purges and solutives cleanse the intestinal glands and promote perspiration internally." The word "alexipharmic," or "alexipharmac," it may be noted, came into use in France in the sixteenth century as a term for a substance to ward off the plague. It first appeared in English in 1605. Sir Thomas Browne (1646) in his *Pseudodoxia epidemica* states "The horn of a deer is alexipharmical." Other alexipharmics were lemon rind, marigolds, scordium, rue, and of course Berkeley's tar water.

It is not possible to say exactly when Williams saw yellow fever in Africa. From his own statement he wrote most of

An Essay on the bilious or yellow fever" in 1745 he mentions the hurricane in Jamaica in 1744 and the expedition to Carthage under Admiral Vernon ('old Grog') and Brigadier-General Wentworth which occurred in March, 1740-1. Williams considered that Bennet was a newcomer in 1750, although Bennet had been in Jamaica since 1746. It seems improbable that Williams would have scorned the views of newcomers in 1745 had he been in Jamaica only four or five years. Williams would therefore have been on board a Guineaman some time between 1730 and 1740, and his description of yellow fever in Africa must antedate that of Schotte by at least 40 years. Roderick Random, it may be remembered, served on a Guineaman after leaving the Navy, where he had acted as a surgeon's mate during the attack on Carthage. Actually Tobias Smollett was in Jamaica from 1741 to 1744 he married Ann Lascelles in 1747, the original of Narcissa in *Roderick Random* and a Jamaican heiress.

#### Parker Bennet and John Williams

Of John Williams no biographical details are available apart from those given in his three works: the "Essay," the "Epistle to the Honourable Charles Price," and the "letter to Dr Bennet." Of Parker Bennet it has been possible to find out a little more. The register of the Church of St Anthony, Montserrat, contains under the date Oct 25, 1725, the baptism of 'Parker son of Mr Edw<sup>d</sup> Bennet and Jane, his wife'."

In the list of graduates of Edinburgh for the year 1745 is the name of Parker Bennet ab Ins S Christoph. This explains his statement that "some of us have been in other islands of the West Indies." Bennet does not seem to have been in West Africa. There were, it may be noted, only two other doctors of medicine in that fateful year in Edinburgh, Ebenezer McFait, Scoto-Brit, and "Robertus Willan, Anglus." Parker Bennet's Thesis, or, as it was then called, his "Dissertatio Medica Inauguralis," was entitled "De Menstruis" and was dated June 18, 1745. It was printed in Edinburgh by W and T Ruddiman. Bennet's name was spelt on the title page "Bennett." His name spelt, however, with one 't' is found in a manuscript record book of scholars, masters, and apprentices now in the library of the University of Edinburgh. This book was apparently begun by Alexander Monro, primus. It gives no address for Bennet, but records that he had paid the fee of three guineas and that his master was Alexander Cunningham. Bennet must have graduated before he was 21 but there were then no regulations and an M A was often taken at the age of 15 or 16. Robert Hamilton, of King's Lynn, appears to have taken his M D in 1791 at the age of 17.

It is not necessary here to follow the gradually mounting tension shown by each succeeding production from the pens of John Williams and Parker Bennet, a progress from the retort courteous to the lie direct. One instance must suffice, Williams in his epistle to Charles Price (afterwards Sir

Charles Price, Bt, Speaker of the Jamaica House of Assembly) refers to "Bennet, whose trifling writings no point hit, That fop in learning and that fool in wit" Two accounts of the final episode have been found one in the *Gentleman's Magazine* for 1751, vol 31, p 136, and the other as an introduction to the literary remains of John Williams and Parker Bennet. Both descriptions are anonymous but are probably by the same hand. The second is entitled, "An authentic account of the death of the unfortunate doctor Williams and doctor Bennet of Kingston in Jamaica, on the 29th of December, 1750, caus'd by the following Papers" As it is short it may be given *in extenso*

"After a great deal of ill language they proceeded to blows, which caused challenges and acceptance, and the morning after doctor Bennet went arm'd with his sword and a brace of pistols to doctor Williams's door very early, and knocked him up, Williams saw from his window who it was, and what he had to expect, upon which he loaded his pistols with Goose, or Swan shot, and slinging his drawn sword by a ribband upon his wrist, came down, and opening the door, just sufficient to admit his hand with a pistol, poured a shot full into poor Bennet's breast, who had delivered his own arms to his boy, whilst he called Williams out, which when he had done, he continued to pursue Bennet, reeling to his boy, and wounded him with the other pistol in his knee. Bennet by this time had gained his sword only, which was fastened so strongly in the scabbard, that with all his endeavours he could not draw it. When Williams had fired his second pistol, Bennet turned upon him, thanked God he had power to be reveng'd, and whilst he endeavoured to release his imprison'd weapon, begged of God to invigorate him a few moments, but Williams then gave him a mortal thrust under his right arm, which pierced the lungs on both sides, having done this he was turning to run for it but that moment Bennet drew his sword, and made a pass at Williams, which entering under the right clavicle or collar bone, pierced the internal jugular vein, and finished its course in the shoulder blade, breaking off at the place of entrance, however, Williams run ten or fifteen yards and then fell, suffocated with his blood, and never spoke more. The unfortunate Bennet survived him about four hours, and then expired, in the most agonizing pains imaginable."

So ended the careers of "the eminent physicians," John Williams and Parker Bennet. Williams has one title to fame in that in 1750 he first recognized that yellow fever was the same disease in the Old and New Worlds. It was not till 1928 that his findings were conclusively confirmed by Theiler and Sellards.

My thanks are due to Mr L. W. Sharp, Librarian to the University Library, Edinburgh, and to Mr S. H. Watkins for information and help in preparing this paper.

## Reviews

## PIONEERS OF SOCIAL MEDICINE

*Some British Pioneers of Social Medicine* By Major Greenwood, D.Sc., F.R.C.P., F.R.S. University of London. Heath Clark Lectures, 1946 delivered at the London School of Hygiene and Tropical Medicine (Pp 118 12s 6d.) London. Geoffrey Cumberlege (Oxford University Press) 1948.

"For many parts of nature can neither be invented with sufficient subtlety, nor demonstrated with sufficient perspicuity, nor accommodated unto use with sufficient dexterity, without the aid and intervening of the mathematics" Professor Major Greenwood confirms this statement of Francis Bacon (*Of the Proficiency and Advancement of Learning* Book II) in this delightful book which embodies the Heath Clark lectures delivered to the University of London in 1946, for vital statistics are the touchstone of public health and social medicine. "I shall write more about 'sums' and less about laws than he [Simon] did," says the author in his introduction. He has therefore selected for his purpose those pioneers who laid the foundation of scientific vital statistics, which in our own time he has done so much to develop.

Though his FitzPatrick Lectures were on the history of medical statistics from Graunt to Farr, he alludes only briefly to the seventeenth-century pioneers and passes to the eighteenth century, by the end of which elementary statistical methods were practised widely, and the pioneers of that century—Howard, Lettsom, Percival, and Ferriar—based most of their arguments on statistical reasoning. The next exemplar is Thomas Southwood Smith, "the most attractive of the pioneers as a human being." It matters little that Smith's epidemiological doctrine is now as obsolete as that of Galen. It was Smith, with his colleagues Neil Arnott and James Phillips Kay, who demonstrated the evils of disease, poverty, insanitation, and ignorance. Chadwick, Shaftesbury, and Morpeth fired the guns, but these medical pioneers supplied the ammunition. There follows a well etched study of the autocratic Edwin Chadwick, a reformer in a hurry, intolerant of public opinion. Chadwick's statistics are open to criticism, less so the conclusions he drew from them in the cause of sanitary reform. But by the time of William Farr, to whom two chapters of the book are devoted, the foundations of national vital statistics were well and truly laid. Farr made the dry bones of figures live by his gifts of literary exposition and showed how they pointed the way to practical methods of prevention, though Professor Greenwood does not think that he was so great as a pure epidemiologist as he was as a general vital statistician.

In the study of John Simon he emphasizes that early scientific training benefited his official work, that he combined scientific research with the work of preventive medicine, chose admirable and competent investigators, and that the Privy Council epoch (1858-72) was his golden age. The last chapter of the book is on Florence Nightingale and Francis Galton. The former pressed for statistical education, the latter invented the calculus of correlations and other aids to statistical research. In Appendix II "The Epidemiological Future," the author consoles us by observing that epidemics of acute infection, such as measles, have never "wiped out" nations or even cities. This is a book to buy to read and to keep.

ARTHUR S. MACNALLY

## TAR DERMATOSES

*Dermatoses among Gas and Tar Workers* By William David Jenkins J.P., B.A. M.R.C.S., L.R.C.P. (Pp 54, 19 illustrations 25s.) Bristol. John Wright and Sons. 1948.

This monograph published two and a half years after the death of the author, fills an important gap in industrial dermatology. It is of value not only for the information that it imparts but because it reveals a research technique of a high order. The lucid description of the processes and the hazards of the coal-gas and tar industry, the careful classification of some 6,600 employees according to occupational environment, the clear and painstaking account of the various lesions in relation to industrial history, and the compilation of the statistical data are all evidence of a clear mind and an acute power of observation.

The work is divided roughly into three sections. The first is on the carbonization of coal and the distillation of tar, and the author exposes some of the mysteries associated with these complex chemical changes. In the second he gives a clinical survey of occupational dermatitis in the industry, and in the third describes the neoplasms resulting from contact with pitch, tar and allied products. He also gives sound practical advice about treatment and prophylaxis. It may be surprising to learn that contact with tar and pitch is not particularly conducive to the development of incapacitating dermatitis, but our own experience confirms this contention.

As with most first publications of this kind, it is not difficult to criticize. For example, we should like to have heard more of the aetiology of tar erythema and the chemical photosensitizers responsible for this temporary though painful reaction. Pitch and tar melanosis might have been discussed more fully, and also "shagreen skin". Moreover, though the account of papillomata and epitheliomata is full and comprehensive, the author does not mention the active carcinogen (3,4-benzpyrene) present in tar and pitch. No doubt these deficiencies (together with the provision of an index) would have been remedied but for the untimely decease of Dr Jenkins. The quarto-sized volume is attractively printed on art paper, and the photographs though not in colour, are clear and instructive. It will be welcomed by all who are interested in industrial medicine and dermatology.

PHILIP ROSS

### **PATHOLOGY IN THE TROPICS**

*Manuel de Pathologie Exotique*. By C. Mathis and R. Pons. (Pp. 642. Cloth covers 1,400 francs, paper covers 1,000 francs.) Paris: Presses Universitaires de France, 1948.

In the last ten years we have probably seen more important advances in the control of tropical diseases than in any other decade in history. It is therefore with considerable interest that one opens a new textbook of tropical medicine, more especially one which purports to consider "the most recent advances in aetiology and therapeutics". Unfortunately one cannot fail to be disappointed, for, although it is published in 1948, internal evidence shows that the greater part of the book must have been written when France was cut off from the outer world.

To mention a few of the more obvious omissions—the new antimalarial drugs paludrine, chloroquine, and nivaquine are dismissed in three lines in a footnote; the quinine treatment of malaria receives two pages. The only drawback to mepacrine is said to be the yellow discoloration of the skin. The use of pentamidine or in fact of any of the aromatic diamidines receives no mention in the account of the treatment of kala-azar or in that of the treatment and prevention of sleeping sickness. The only drugs mentioned for the treatment of amoebic dysentery are emetine hydrochloride, bismuth salicylate, neoarsphenamine, and acetarsol. Sulphones are not referred to for the treatment of leprosy. Penicillin finds no place in the treatment of tropical ulcer and yaws and in the latter disease bismuth salts, which are the cheapest drugs for mass treatment, are recommended only when the spirochaetes are resistant to arsenicals. In the treatment of rickettsial infections para-aminobenzoic acid is unknown; it would be too much to expect an account of chloromycetin. Sulphonamides are not mentioned for the treatment of lymphogranuloma venereum. Even when the authors advise using penicillin as in the treatment of staphylococcal infections they recommend that it should be given intravenously or subcutaneously. In addition to the omissions from the sections on therapeutics there are many other failures to take notice of recent advances, and many errors. The authors do not even hint at the existence of exoerythrocytic forms of malarial parasites though they give much attention to the life history of plasmodia. They dismiss DDT in two short paragraphs: fish are said to be preferable for destroying mosquito larvae. Neither Paris green nor gammexane seems to be known. No mention is made of recent work on black-water fever. Instead we are told that it is specially prevalent in wooded valleys. The account of yellow fever is totally inadequate. The authors emphasize the highly debatable point that yellow fever attacked the Spaniards on the discovery of Haiti but give no account of any epidemic of yellow fever among African natives since that in the late twenties. The enormous

outbreak in the Sudan in 1940 is not mentioned, nor is the wide geographical extension of the disease to the east coast of Africa and as far south as Northern Rhodesia. The role of monkeys in maintaining infection is apparently unknown, and no mention is made of insect vectors other than *Aedes aegypti*. Under the heading of tissue culture the only reference is to the attempt by Haagen and Theiler (1932) to grow the neurotropic strain of the virus. The use of the virus 17D for immunization is dismissed in a few lines and is recommended only for children in whom it is recognized that the neurotropic strain causes dangerous reactions. Similar errors and omissions mar the chapter on rickettsial infections: neither Q fever nor rickettsial-pox is mentioned. To continue to cite further examples would only be tedious. A short but useful account is given of cosmopolitan diseases in the French colonies, but curiously enough infective hepatitis is unnoticed and no reference is made to the frequency of cirrhosis or of primary carcinoma of the liver. Poliomyelitis is said to have been introduced between 1920 and 1925. Beriberi is the only deficiency disease to which attention is drawn despite the malnutrition widespread in many French African colonies.

The book is well printed and produced and has an index, but its contents, in view of the claim to discuss "the most recent advances in aetiology and therapeutics," can serve only to point the moral of many of the discussions at the recent Royal Society Conference on the dissemination of scientific knowledge.

G. M. FINDLAY

### **AMBULATORY SURGERY**

*Surgery of the Ambulatory Patient*. By L. Kraeer Ferguson, A.B., M.D., F.A.C.S. With a section on fractures by Louis Kaplan, A.B., M.D., F.A.C.S. Second edition. (Pp. 932, 645 figures. £3 12s.) Philadelphia and London: J. B. Lippincott Company.

When the first edition of this book appeared in 1942 it was welcomed in this *Journal* because it seemed to fill the gap which existed between the usual handbooks of minor surgery and the full surgical textbooks. We noted then that the adjective ambulatory had been interpreted liberally and suggested that some of the conditions described were rather more severe than those it was customary to treat in the out-patient departments in Britain. But the increasing shortage of in-patient accommodation may force us to change our habits and to extend our ambulatory treatment to the wider limits indicated in this book.

The second edition maintains the virtues of the first but has been brought up to date without increasing its size; it includes accounts of such important new topics as the use of penicillin and the sulphonamides, tendon suture, and lesions of the back. There is much information in these pages that one may search for in vain elsewhere, and the teaching is sound. Some omissions have been needed to make room for the new matter, for the most part they are unimportant. However, there is one of interest we could not help regretting although it has no practical application in this country—the intriguing story of the black widow spider. Having destroyed its smaller consort immediately after mating it lurks under the seats of privies awaiting an opportunity to inflict painful and even dangerous bites upon the perineal regions of those seated thereon. Are such cases no longer met with in the USA? Have the privies now been rendered safe for democracy? The author of this very useful and commendable book does not enlighten us on this point.

NORMAN C. LAKE

### **FOUNDATIONS OF HEALTH**

*The Foundations of Health in Childhood*. By Norman B. Capon, M.D., F.R.C.P. The Convocation Lecture, 1947, of the National Children's Home. (Pp. 76. 2s. 6d.) London: National Children's Home and Orphanage, Highbury Park, N.

Childhood is essentially the period of growth, and Professor Capon regards the attainment of optimum health in each organ and system—"wholeness of structure and function"—as essential to the foundation of health in childhood. He outlines influences which by operating during antenatal existence, birth, or infancy and childhood, may and do interfere with the realization of that aim.

Measures for establishing health in childhood must not be purely defensive or protective. The author discusses in simple terms a child's nutritional requirements, his needs for active

games and exercise under conditions favouring health and limiting the risks of accidents, and factors related to the elements of hygiene to conditions of environment, and to lessened risks of exposure to infection. If these received more attention the health of the nation's children would be on a surer foundation. He recognizes that there is no one solution to the many outstanding problems. Education for health in childhood must continue unabated. The conditions under which children live, learn, eat, sleep, and play must be improved regardless of the sociological and economic problems involved. A proper appreciation of the true values of life must be encouraged. It is significant that in the concluding chapter, on the attainment of optimum health, Professor Capon describes needs which, while they are not essential to the continuance of life, are of the deepest significance in promoting and maintaining optimum health in childhood. These needs are for home life, happiness, opportunities for physical, mental, and emotional development and the stimulus of good example.

This is an admirable book and should have a wide appeal. The author presents the needs of child health in simple and unbiased fashion. He depicts the child as one who should be enabled to attain optimum health in his own home. From first page to last the reader will appreciate how workers in the field of child health must pool their efforts if this ideal is to be attained. The tenor of Professor Capon's lecture cannot but encourage just that co-operation. Those who promoted the lectureship are to be congratulated on making this valuable address available in published form. Readable and modest in price, the book should be on the shelves of all family doctors, infant welfare and school medical officers, and social workers concerned with children.

W S CRAIG

### VOLUNTARY SOCIAL SERVICES

*Voluntary Social Services Since 1918* By Henry A. Mess *et al*  
Edited by Gertrude Williams. International Library of Sociology and Social Reconstruction (Pp 255 21s) London  
Kegan Paul Trench Trubner and Co 1947

The title of this book is slightly misleading, for there is a great deal of information in it about the voluntary services in the earlier part of the century. This is a fault in the right direction for it gives a deeper perspective. The reviewer came to the conclusion that the book is even more valuable for the inferences drawn from examining the various agencies than for the great volume of information given about them. Their number and variety are amazing. The late Henry Mess, who wrote much of the book and inspired his colleagues, finds no legal definition of a social service but suggests that it is "a benefit which is being conferred on those who are relatively less well off or relatively unprivileged in some way." The authors demonstrate that the work of voluntary agencies is shifting from the remedial, which is now mainly in the hands of the State, to the constructive. None of the ten contributors has any doubt that there will always be a place for voluntary workers. They pay generous tribute to their pioneer efforts, and the fact that many of them have, so to speak, dug their own graves is no reflection on their capacity, for "all voluntary organizations and all social services should aim at destroying the need for their existence. The main characteristic of such organizations is their flexibility which gives them the advantage when dealing with individuals. This flexibility is shown, too, when they come to co-operate with the State agency which has taken over their work, for it has tended to humanize the official body and make it more inclined to experiment."

The chapter by Henry Mess on "Social Service with the Unemployed" is exhilarating to read, it obviously came from the heart as well as from the pen of a man who had a unique experience of the experiments made during the black years of mass unemployment. He came to the conclusion that "the State can only embody the desires of contemporary Society. The Voluntary Association is not thus cabined and confined. Its proper task is always to give expression to the questing spirit of mankind."

The book can be cordially recommended not only as a mine of information but as a tonic for anyone who feels doubtful about the capacity of our people to rise to any emergency which requires kindness, initiative, and public spirit. It is not only war that can bring out these virtues. Mr Mess's chapter was an eye-opener to one of his readers.

ALFRED COX

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Feeding the Human Family* By F. Le Gros Clark, M.A.  
(Pp 125 7s 6d) London Sigma 1948

An account for the layman of food production and distribution

*Headache and Other Head Pain* By H. G. Wolff, M.D.  
(Pp 642 63s) London Geoffrey Cumberlege 1948

An analysis of the pathology and symptomatology of headache

*Pharmacology and Therapeutics in Nursing* By M. S. Dooley, M.D., A.B., and J. Rappaport, R.N., B.S.  
(Pp 444 22s 6d) London McGraw Hill 1948

A textbook for nurses

*Nursing in Diseases of the Eye, Ear, Nose and Throat* Edited by D. H. Webster, M.D., *et al* 8th ed (Pp 309 15s) London Saunders 1948

A textbook for nurses, with much new material in this edition

*Studies in Analytical Psychology* By G. Adler, Ph.D. (Pp 213 21s) London Routledge 1948

Studies based on the author's fifteen years' practice of analytical psychology

*Changing Disciplines* By J. A. Ryle, M.D. (Pp 122 12s 6d) London Geoffrey Cumberlege 1948

Lectures on the history, methods and motives of social pathology

*Nursing in Tuberculosis* By L. N. Cady, R.N. (Pp 481 20s) London Saunders 1948

For the qualified or student nurse

*Promotion from Primary to Secondary Education* By D. M. McIntosh, M.A., B.Sc., B.Ed., Ph.D., F.R.S.Ed. (Pp 151 1s) London University of London Press 1948

A summarized account of an investigation by Professor W. W. McClelland, of St. Andrews University published under the title "Selection for Secondary Education"

*Clinical Laboratory Methods and Diagnosis* By R. B. H. Gradwohl, M.D., D.Sc., F.R.S.T.M. and H. 4th ed Vols I, II, and III (Pp 1,295, 2,284, and 864 \$40.00 for 3 vols) St. Louis Mosby 1948

A textbook of laboratory procedures used in diagnosis this edition contains much new material

*The Radiology of Bones and Joints* By J. F. Brailsford, M.D. Ph.D., F.R.C.P., F.I.C.S. 4th ed (Pp 760 63s) London Churchill 1948

This edition contains revisions and additions

*Cardiography* By W. Evans, M.D. D.Sc. F.R.C.P. (Pp 132 25s) London Butterworth 1948

The author discusses electrocardiography and phonocardiography and includes many cardiograms

*Rural Health and Medical Care* By F. D. Mott, M.D., and M. I. Roemer, M.D., M.P.H. (Pp 608 39s) London McGraw Hill 1948

A study of the medical services in rural areas in the U.S.A.

*A Handbook of Ophthalmology* By H. N. Caine, F.R.C.S., and F. A. Williamson-Noble, F.R.C.S. 6th ed (Pp 336 21s) London Churchill 1948

Intended for students and general practitioners

*Emergency Surgery* Part II By Hamilton Bailey, F.R.C.S., F.A.C.S., F.I.C.S., F.R.S.Ed. 6th ed (Pp 388 21s) Bristol Wright 1948

This part is on surgery of the abdomen

*Procedure in Examination of the Lungs* By A. F. Kraetzer M.D. 3rd ed (Pp 150 18s) London Geoffrey Cumberlege 1947

An introduction to the technique of examining the lungs for the student

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 4, 1948

## SCIENTIFIC MEDICINE IN BRITAIN TO-DAY

Sir Henry Dale is the acknowledged leader of scientific thought in medicine in these islands. His activities in research have ranged over an enormous field in nearly half a century of service. In the experimental approach to physiology, pathology, and pharmacology his genius is representative of the best British tradition. His lecture on accident and opportunism in medical research, which appears in our opening pages, is a notable introduction to the series of articles on research specially contributed to the present Educational Number.

Professor L. J. Wits writes on the problems of clinical research in the light of a rich personal experience. He emphasizes the need for the trainee investigator to spend at least a year in a non-clinical department—it might be in biochemistry under Sir Charles Harington, or possibly learning about statistics to make up for what Professor Major Greenwood might regard as a defect in his undergraduate education. In his wide-ranging discussion the place of physiology and the physiological outlook scarcely receive the emphasis they deserve. The change in medical thought in our generation from its concern with structure to concentration on function has thrown a flood of light on present problems and given us high hopes for the future. At the end of the last century the scientific basis of clinical medicine lay in morbid anatomy and pathology, and German medicine was predominant. British medical science did not take kindly to this emphasis on structural change or to the meticulous cataloguing needed for the pathological documentation of disease. Our genius lay rather in the study of the dynamics of living processes, then being pursued mainly in the laboratories of animal physiology. It will be recalled that Sir Henry Dale's senior and junior contemporaries at the beginning of this century included such men as Gaskell, Langley, Sherrington, Schafer, Fraser, Bayliss, Starling, Barcroft, Adrian, Hill, Haldane, Macleod, and Cushny. Fifty years ago clinical medicine was for the most part a subject separate from or unconnected with physiology. It was concerned with the natural history of disease so far as it could be recognized and classified by the patient's history and by the evidence of almost unaided eyes, ears, and hands. Then a great step forward was made when J. S. Haldane carried out his beautifully designed experiments on the control and regulation of respiration, using himself and his colleagues as experimental subjects. James Mackenzie, in his general practice in Burnley, at about the same time was carrying out his phenomenal single-handed feat of analysing cardiac irregularities with especial reference, as Dr W. N. Pickles emphasizes, to prognosis. Mackenzie's only technical help

came from a co-operative local watchmaker. He and Haldane established the possibility of accurate scientific observation on man in medicine and in physiology. It was with Mackenzie's powerful help that Thomas Lewis embarked on scientific medicine as a career. The application of scientific method at the bedside was pursued by Lewis almost in splendid isolation over a period of nearly 20 years, but gradually, between the two great wars, an increasing number of investigators found their inspiration in Lewis's example. He not only inculcated a strict scientific discipline in those who were personally associated with him, but he managed to secure the allocation of funds for direct scientific investigation of the problems of disease. This he effected through the Royal Society and the Medical Research Council, whose work is so clearly outlined elsewhere in this issue by Dr F. H. K. Green. Concurrently with these developments the University of London and medical schools in other parts of the country established whole-time professorial units to enable their staffs to pursue studies in medicine with the advancement of knowledge as a primary duty. These units, now widely distributed, are in spite of many difficulties live catalysts of inquiry in our medical schools. Of these developments and of the achievements of our research workers we can feel justly proud.

In the United States there has been a tremendous growth of scientific medicine along somewhat similar lines, but with the difference that far greater numbers are engaged in work of this character. What Dr Raymond Whitehead in his account of medical education in the United States refers to as an "abundance of teachers" is matched by a corresponding abundance of research workers. But the increased volume of work done in America is due not so much to larger numbers of whole-time university workers as to the spread of the spirit of scientific inquiry among consultants generally. The pace at which research is pursued in the United States is at times staggering, but quantity does sometimes overwhelm quality. A happy mean must be found between the rather casual attitude of some of our specialists to laboratory research and the highly competitive transatlantic drive to produce a paper a year.

Professor Wits is rightly concerned about the ethical problems of investigation in man, and draws a distinction between experiments on healthy volunteers and those therapeutic trials on patients which are often among the highest services that medicine as a science can render. Lewis himself and all who follow him insist that the sick man's interests must be paramount, and where research is pursued it must be accompanied by considerate kindness, forbearance, and sympathy with the patient. There are many who are by nature disinclined for detailed laboratory analysis of the physiological problems presented by disease but who are attracted by equally important studies of the influence of environmental conditions on the patient's health. This approach has grown to-day into social medicine, but social medicine and clinical science are collateral studies and in no sense mutually exclusive.

The way in which fundamental biological and biochemical research impinges on medicine is outlined in the article by Sir Charles Harington. In spite of Professor Wits's inclination towards animal experiment as an adjunct to clinical research, it is still the primary duty of the scientific clinician to study disease in man. There is no laboratory method of inducing diabetes, or for that matter

cirrhosis of the liver, which is *exactly* comparable to the clinical condition. At best we get only crude approximations. There should be a constant transference of questions from clinical medicine to the animal laboratory, whence ideas will return to the clinic, but the clinical investigator clearly cannot be as expert in the pursuit of pure biochemistry or experimental pathology as those who have specialized in such work.

The methods now available for the study of physiological reactions in living man in health and disease were undreamed of fifty years ago. We can now locate areas of functional activity in the brain, we can use radioactive iodine to evaluate the activity of the thyroid gland, we can measure the output of the heart, and all the activities of the lungs, we can outline the individual chambers of the heart by the injection of radio-opaque substances, and the newest electrocardiography permits an accurate location of areas of heart disease. Important parts of the alimentary tract and urinary tract can be viewed directly, blood flow in the liver, kidney, and brain can be estimated, and the functions of renal glomeruli and tubules can be analysed. Beyond this is the great realm of direct applicability of biochemistry, with the possibility of estimating an ever-increasing number of metabolic and endocrine functions. Medicine is now, in fact, a science in its own right, making use of almost all the techniques of the basic sciences. The methods are there, the problems are legion, and for the intelligent investigator the harvest of results will be rich. The future is in our hands, and there is no reason why the high tradition of research in British medicine should not be fully maintained under the altered conditions which since July 5 have changed the pattern of medical practice. The financial prospects for the keen young worker in clinical medicine were probably never more promising. It is widely agreed that the training of the clinical specialist should include a minimum period of a year in the acquisition of research discipline. This is a wise recognition of the need to establish habits of deep thought and scholarly reflection, a critical outlook on the flood of papers which pours from the medical press, and humility in the face of the unknown. But if the fundamental sciences on which medicine is based are to be well served by acute minds the universities must revise their conception of what a living wage for an educated man should be. University departments of physiology, pathology, pharmacology, anatomy, and biochemistry must be able to attract the medical graduate who has taken an honours degree in science, for it is in these departments that the fundamental discoveries will for the most part be made. The medical profession must press upon the universities the implications of the Spens recommendations for consultants and specialists.

By its very nature medicine must always make use of inductive reasoning—facts being collected and arranged until some general pattern is seen from which a tentative generalization may be made. Many of our generalizations are built in this somewhat insecure way, and as new facts make their appearance we tend to be unwilling to cast aside the old hypotheses that have served us well. It is only by careful and detailed consideration of stubborn facts that we can create new ideas. The ideas themselves must be subjected to constant testing by new techniques, constant revision, constant design of new experiments. This is the way in which the stream of knowledge is kept alive.

## INTERNATIONAL CAUSES OF DEATH

Research does not start of itself, and discoveries are rarely made accidentally. Some stimulus is required, and the need for research on a particular problem is often demonstrated in the first instance by the tabulation of classified statistics. In the field of preventive medicine this is almost a truism, but in therapeutics the part played by the patient collection of figures often goes unrecognized. This applies also to the work which has been done in the past on the compilation of nomenclatures and classifications of diseases.

The International List of Causes of Death, which has now undergone six decennial revisions, is still almost unknown outside public health offices. The new International List<sup>1</sup> now includes non-fatal diseases, minor ailments, and different kinds of injury, and the decisions of the first World Health Assembly about its use marks the beginning of a new era of morbidity statistics. The distinction between a nomenclature and a classification is not always understood. A nomenclature is concerned with what are believed to be the different entities of disease in the light of medical knowledge at the time of its compilation and with the most suitable names for them. Alternative less suitable, and out-of-date names for diseases find no place in it, nor do vague and ambiguous terms no matter how common their usage may be. A nomenclature represents an ideal which the medical profession is asked to aim at, but its absorption by the profession as a whole is a long process, and by the time it has been absorbed and adopted by the majority the nomenclature is already ripe for revision. Physicians and surgeons who are to-day writing medical certificates and records received their training at all periods throughout the past half-century, and the labels they have been accustomed to attach to varieties of illness will be only partially changed by the issue of a new nomenclature. A statistical classification of diseases, however, has to provide a place for every term and description of illness and injury which is being written on certificates and records now, whether it be good or bad, modern or effete. Furthermore, the grouping, while being as near to an ideal one as possible, has to be designed to give the greatest possible help to the present problems of preventive medicine and research. For these reasons a nomenclature will not serve the purpose of a statistical classification, and neither that of the Royal College of Physicians nor the Standard Classified Nomenclature of Logic was intended to do so.

At the time of the Paris Conference for the Fifth Revision of the International List in 1938 the need for a full classification of diseases and injuries for morbidity statistics was beginning to be felt, and the U.S. Government was asked to study the question in consultation with other nations interested. The outbreak of war made the preparation of such classifications imperative, and in this country as well as in the U.S.A. and Canada provisional classifications were prepared. The Medical Research Council's *Provisional Classification of Diseases and Injuries*, which started from a draft prepared by Stocks and Robb-Smith, was tried out for E.M.S. hospital records in 1943 and was published in 1944, the U.S. Public Health Service *Manual for Coding of Illness* was published about the same time. It was fortunate that each of these lists was built into the framework of the International List of Causes of Death, and that

<sup>1</sup> *International Statistical Classification of Diseases, Injuries and Causes of Death*. WHO IC/MS/I Rev. 1, 1947. Geneva.

they all had sufficient resemblance to suggest that an international classification might be constructed to serve the purposes of both mortality and morbidity. Since 1940 cause-of-death statistics had been founded upon the underlying condition which eventually led to death, and there was no logical reason why conditions which did not prove fatal could not be classified on the same basis and with the same code numbers as those which did. The General Register Office agreed, therefore that an attempt ought to be made to compile such a classification. The U.S. Government then set up a Committee on Joint Causes of Death and at the end of 1945 invited representatives from Britain, Canada, and the League of Nations to discuss the problem of joint causes and the preparation of a classification applicable to morbidity. The latter task was given to a working party, including Stocks, Robb-Smith, and Biraud, which laboured for two months in Washington. Agreement was reached, and it was decided to submit the result for criticism by numerous medical organizations and specialists in the English-speaking countries with a view to offering it for the Sixth Revision of the International List due in 1948. In this country the Minister of Health appointed a committee with Sir Ernest Rock Carling as chairman to study the project and to prepare a tabular list of the principal conditions to be included in each category of the list. At Ottawa in March, 1947, the U.S. committee met again, reached agreement on the numerous amendments submitted, and presented the classification to an expert committee established for the purpose by the Interim Commission of the World Health Organization. That committee, with the Chief Medical Statistician of the General Register Office as its chairman, circulated the list to 70 Governments.

At a second session of the expert committee in Geneva the comments from some 40 nations were carefully considered and incorporated so far as possible. The finished product was again sent to Governments with an invitation to the International Conference for the Sixth Revision of the List of Causes of Death at Paris in April of this year. At that conference 29 nations were represented and the expert committee suggested that the Classification be adopted unanimously at the outset. Not only was that done but all the committee's recommendations for the use of the detailed and abbreviated lists were accepted in principle and other plans for international studies were made. The conference also accepted the proposal of the U.S. Committee on Joint Causes of Death that a form of death certificate enabling the certifier to decide which was the underlying cause (almost identical with that used by the General Register Office) should be recommended for international use, thus removing a serious source of discrepancy between the mortality statistics of different countries.

The First Assembly of the World Health Organization set the seal on all this work by accepting the recommendations of its expert committee and of the Paris Conference, and by deciding upon a set of international regulations for the use of the Classification for all purposes from 1950 onwards. In this country as well as in Canada and the U.S.A. its use for national morbidity statistics in 1949 is anticipated. The *International Manual*, which is being printed in Geneva in three languages, will contain a historical introduction, the detailed list of categories, each denoted by a three-figure code number, a tabular list of the principal included conditions with suggested (fourth figure) subdivisions of many of the categories, abbreviated lists for special purposes, the

recommended form of death certificate and rules for coding when more than one cause is stated upon it, and the international regulations. A second volume, now in preparation, will contain an alphabetical index of over 20,000 terms likely to occur on medical records of all kinds.

### THE DOYEN OF BRITISH OPHTHALMOLOGY

The September issue of the *British Journal of Ophthalmology* is a special number marking the eightieth birthday of Sir John Herbert Parsons. Fittingly the volume is a large one containing twenty-three articles by authors from many countries. Some of them are his friends and contemporaries, more of them are former students of his. In tribute to his many-sidedness there are three introductory appreciations, by Professor E. D. Adrian representing science and particularly physiology, by Professor J. van der Hoeve, of Holland, representing the International Council of Ophthalmology, and by Mr. R. R. James as the senior editor of the *British Journal of Ophthalmology*.

There are few people in British medicine who can look back upon eighty years of life crowded with so many diverse interests and so replete with accomplishment. Most of us are content with one main activity whether it be clinical work, fundamental research, or public life. To few is vouchsafed the ability to be at the same time a leader in all three. During his long working life Sir John Parsons from the clinical point of view was the foremost ophthalmological consultant in this country and his reputation as a pathologist in his special field was exceeded by no one in any country of the world. He is still a recognized authority on the basic problems of natural science as they affect vision. During his most active period his advice and help were sought by the Government and by industry on all the varied problems in which vision is concerned. He served in the two world wars in 1914-18 in an active capacity as ophthalmological consultant to the Army, more recently in an advisory capacity for the Air Force. Sir John Parsons was the dominant figure in British ophthalmology for many years, organizing teaching, guiding research, and exerting a leading influence on questions of policy and in international ophthalmology he was a constant and acceptable British ambassador. To all these activities was added an exceptional literary output, and among a wealth of scientific and clinical papers three books of his will remain classics. His four-volume *Pathology of the Eye* published at the beginning of the century and still unsurpassed came first, his book on colour vision was first published in 1915, and is still the most masterly and unbiased analysis of a subject till then chaotic. Most important of the three his *Introduction to the Theory of Perception* appeared in 1927, and assembled the biological, psychological, and clinical materials of a complex problem, which has excited speculation since the time of Descartes, into a unitary philosophy, the importance of which is not yet fully appreciated.

It is good that Sir John's abilities, his constant efforts, and his great human qualities should have brought their reward in his lifetime. In his public work he was honoured by the State, and for his scientific work he was made a Fellow of the Royal Society. Every position of distinction and every prize that ophthalmology has to offer has been his, and his general medical interests were recognized when he was elected President of the Royal Society of Medicine. It is more important to remember, however, that he has moulded the thought and earned the gratitude and warm affection of more than one generation of ophthalmologists. On his eightieth birthday this feeling has found expression, through the Faculty of Ophthalmology and the Ophthalmological Society of the United Kingdom, in the presentation to him on Sept. 3 of his portrait in oils.

## THE THRESHOLD OF PRACTICE

The proposal that an intern year—or, more exactly, a period of clinical experience under supervision—be added to the curriculum before the newly qualified doctor goes out into independent practice is supposed to have been first put forward in the B M A Committee's report on Medical Education, published in 1934. From that time onwards the idea was certainly canvassed in many discussions, revealing a variety of opinion about the length of this consolidating period, the extent and nature of the supervision, whether registration should come before or after, and whether at the end of the year or whatever the period might be there should be an examination. Eventually the proposal came to rest in the Goodenough Report, one of the recommendations of which is that in future the entry upon independent practice shall be preceded by a compulsory period of approved and supervised clinical work. This was embodied in the draft Medical Bill submitted to the Minister of Health by the General Medical Council, and it was endorsed by the Curriculum Committee of the B M A, which reported this year, and which put forward suggestions on the best way in which the year could be used.

It was therefore a little interesting to come, quite by accident, upon an old article signed "CA"—a reference to a list of contributors shows that the author was the late Sir Clifford Allbutt—buried in the *Encyclopaedia and Dictionary of Education*, published in four volumes in 1922. Sir Clifford Allbutt's article is only a brief one, but in it he puts forward the proposal for the adoption in British medical education of a compulsory year, after qualification, of general and special practice undertaken "under supervision". It may be of course that Sir Clifford Allbutt was by no means the first to make the proposal. Some investigator may trace it far back in the history of medical education. But if it was Sir Clifford Allbutt it is another example of the foresight of one of the wisest of our modern scholar-physicians.

Allbutt, however, did not seem to contemplate, as do later advocates of the idea, that this period should be spent in hospital. Apparently he saw the newly qualified practitioner taking his extra year under the supervision of a private practitioner, general or special. In the hospital ward, he says, the student cannot learn the many little necessary and useful arts and devices of the successful family physician and the elegant prescriber. He refers to complaints in the correspondence columns of the medical journals of that time that the new assistant, a university man it might be, could not make up a popular cough mixture or suggest pleasant solace for testy old people. Such accomplishments, along with more fundamental teaching and experience no doubt, might be acquired in the extra year. The young practitioner would learn the secret of the doctor-patient relationship—something which cannot be learnt, or learnt as well, on institutional patients.

Another point of interest in that little article of Allbutt's, written a generation ago, is that he appears as an advocate of the one-portal system (though it is necessary to qualify and explain his advocacy). What impressed him was the unfortunate competition, though perhaps unacknowledged as such, between the Conjoint Boards and the universities. In his view the examination for the Conjoint diploma came into competition with the examination for qualifying university degrees, with unfortunate results for both. It meant that in such competition there were an unduly large number of rejections in the Conjoint. That holds good to-day, when the rejections are not far short of 50%, whereas in many of the universities they are more like 25%. At the same time the university degrees by

reverse competition are diminished, and there was a tendency, in Allbutt's opinion, to award them, not as marks of academic distinction but as little more than qualifications for practice, making them rank far below parallel degrees in other faculties. His remedy was the drastic one of proposing two orders of doctors. The one order would comprise the handy-men, well up in the ordinary standards of the day, dextrous in family practice, but making no profession of scientific learning. For these there might be one Conjoint examination. The others would be men who had gone through the longer course of the university, and whose education had been on larger scientific lines, and for such the universities would be able to expand their more liberal courses of study and bestow their degrees on candidates conversant with the larger conception and having a grasp of scientific methods. If Allbutt's idea of the supervised year looks like coming to pass, this other idea of his entailing a bisected profession, probably never had much chance of acceptance, and nowadays has less chance than ever.

## MEDICINE AS A WOMAN'S CAREER

Nearly eighty years ago five women, led by Sophia Jex Blake, tried to prevail on the Senate of the University of Edinburgh either to open to them courses of study in the University or to accept certificates for courses arranged for women separately. The University finally decided against the admission of women to degree examinations. A School of Medicine for Women was then founded in London, opening in 1874 with fourteen students, and two years later an Act was passed to remove restrictions on qualification for registration under the Medical Act on the ground of sex. In 1877 Sophia Jex-Blake and others took the final examinations and were placed on the *Medical Register* as licentiate of the College of Physicians, Dublin, having done their clinical work in London or abroad. In 1878 the London degrees were thrown open. Paris was years ahead of any British university in this readiness to examine women in the Faculty of Medicine, and Elizabeth Garrett Anderson took the M D degree there in 1870. The Society of Apothecaries had admitted her to its final examination in 1865, and she had passed it, but the Society subsequently altered its charter so as to prevent other women from following in these intrepid footsteps.

In the new National Health Service there is complete equality of status and opportunity for men and women doctors. Medical women hold responsible posts in the Government service, under the Regional Hospital Boards, and in the employment of local authorities. A recent pronouncement was made to the effect that the position of Chief Medical Officer to the General Post Office will in future be open to men and women alike, previously this post has been available for men only. The field of work in the Colonial Medical Service is increasing for women as well as for men. The women's medical service in India is now closing down. Another field to which many medical women have devoted themselves is missionary service.

The Medical Women's Federation (73, Bourne Way, Hayes, Bromley) is the only professional organization in Great Britain and Northern Ireland consisting solely of registered medical women. It includes twenty-three local associations and has a membership of 2,300. The Association of Medical Women—the forerunner of the present Federation—was founded in 1879. The Federation came into being in 1916. It endeavours to bring before the main body of the profession the special minority difficulties of medical women, and, when necessary, to press for the full application of the principle of equality which has for so long been conceded by the profession as a whole. It works

in close and friendly relationship with the British Medical Association, and strongly encourages more women to take an active part in the work and activities of local Divisions. The Federation is often approached by Government Departments and other bodies seeking the opinion of medical women.

The Federation holds that with equality of opportunity goes equality of sacrifice, and it deplors the Government decision to exclude women doctors from conscription to the medical services of the Crown. Women doctors can volunteer for commissions as specialists, but the Federation feels that they should be called up in the same way as their men colleagues.

### THE LISTER INSTITUTE

The report<sup>1</sup> for 1947-8 of the Governing Body of the Lister Institute of Preventive Medicine, the chairman of which is Sir Henry Dale, is a highly summarized account of work which is being carried on by a staff of about 40 in half a dozen departments. The Institute works in a number of divisions, concerned respectively with bacteriology, serology, and experimental pathology, with nutrition, with biochemistry and immunochemistry, with biophysics, and with the preparation and study of therapeutic sera, vaccine lymph, and bacterial vaccines. It also accommodates for the Medical Research Council the bacterial chemistry research unit, under the direction of Sir Paul Fildes, the national collection of type cultures, and the blood products research unit, and, for the Ministry of Health, the blood group reference laboratory. The blood products research unit during the year tested and prepared 20,000 bottles of dried human plasma for issue to hospitals, and produced 2,400 bottles of fibrinogen, 5,000 bottles of fibrin foam, and 500,000 units of thrombin for clinical use. The blood group reference laboratory examined 8,700 tubes and 3,500 bottles of serum for suitability for blood-grouping serum. Full Rh genotyping tests were carried out on 2,230 specimens of blood, and 1,070 specimens of serum were tested for anti-Rh and other abnormal antibodies. The national collection of type cultures has been reorganized, and a start has been made to bring the collection into line with the Medical Research Council's intention that only cultures of medical and veterinary interest should be maintained. The collection now consists of about 3,000 strains of bacteria, which are being checked for purity. About 200 new strains were added and over 8,000 cultures distributed during the year.

Much of the research work in the Institute is of a continuing character in which no conclusive results are to be expected in a particular year. Records of several of the investigations have appeared in the specialist journals, notably on the sequence of amino-acid residues, the production of stable potent preparations of penicillinase, the metabolism of nicotinamide and related compounds, the biochemistry of bacterial toxins, adsorption experiments with gramicidin and related substances, and electrophoresis in medical research. In connexion with this last investigation workers at the Institute have examined a group of sera from patients having different types of jaundice. It has been established that a small but definite fraction of the bilirubin migrates with the  $\alpha$ -globulin in addition to the bulk of the bilirubin which migrates with the albumin. It has been further demonstrated that the binding of the bilirubin by different plasma proteins bears no relation to the nature of the direct van den Bergh reaction. The distribution of plasma proteins in malnutrition has been determined on a large group of sera obtained from cases of malnutrition in Germany. This forms part of an extensive

general survey carried out under the auspices of the Department of Experimental Medicine at Cambridge.

One of the nutritional studies at the Institute has been an investigation of the effect of vitamin A—or, where it is unsuccessful, moderate doses of vitamin D—on the stomach. Human subjects with peptic ulceration diagnosed radiographically or who have pain without ulceration are being kept under observation. Patients have been obtained through the co-operation of the Post Office medical service—the completeness of the records and continuity of engagement makes the following up of employees relatively simple. Treatment with vitamin A has had no consistent effect on gastric acidity, but the results already obtained are said to confirm the claim of others that great benefit can be conferred in certain cases.

### CHILD HEALTH SERVICES

A survey of child health services in Berkshire, Buckinghamshire, and Oxfordshire has been prepared and published by the Regional Hospitals Council of the three counties.<sup>1</sup> The Council is part of the regional organization set up nearly ten years ago by the Nuffield Provincial Hospitals Trust, and the survey, which is a document of nearly 100 pages, appears under Trust auspices. Professor Alan Moncrieff, the chairman of the Child Services Committee (a committee fully representative of the medical and social services of the region), draws attention in the foreword to the need for a larger place in the medical curriculum for the medical care of children, since in the long run paediatrics can flourish only on a solid educational basis. Research also is needed not only into the fundamental causes of many disorders but also to discover the best means of educating handicapped children—children afflicted, for example, by muscular paralysis or defects of sight or of hearing. The common illnesses affecting the nose, throat, and ears of so many children also need co-ordinated investigation.

In the three counties an analysis made in 1945 showed that 59% of deaths in childhood (including stillbirths) occurred before the age of one month, 21% between one month and one year, and 20% between one year and fifteen years. Infections (particularly pneumonia) cause more than half the neonatal deaths after the third day, and since many of these are the result of obstetrical complications "it can be said that good maternal nutrition and good antenatal and obstetrical services are the principal factors in reducing stillbirth and neonatal rates." In the period from one to fifteen years the causes of death are more varied, but infections (tuberculosis now the principal) account for two-fifths of all deaths. The largest single cause of death in this age range is accidents, chiefly road accidents.

The report describes the present available and the ideal health services for children, and stresses the need for co-ordination between hospitals, medical officers of health, school medical officers, and general practitioners. One suggestion is for routine ward rounds or out-patient sessions by the paediatrician or his deputy, which general practitioners and medical officers could attend informally whenever they had the opportunity. The mental health of the children is considered in a special section of the report. In the area under review about 42,000 children may be expected to need some psychological or psychiatric observation, about half of these will require special tuition only, but some 12,000 will need mainly psychiatric as opposed to psychological help over varying periods of time, and to these must be added 7,000 children who need both psychiatric and psychological attention.

<sup>1</sup> Report of the Governing Body of the Lister Institute of Preventive Medicine, 1948. London.

<sup>2</sup> Obtainable from the Secretary, Nuffield Provincial Hospitals Trust, 12, Mecklenburgh Square, London W.C.1.

## AROUND THE SCHOOLS

## THE ANNUAL RECRUITMENT TO MEDICINE

The yearly additions to the *Medical Register* are once again increasing. Last year 2,787 names were added, an increase of 550 on the year before, and 500 above the average of the last twenty years, though rather below the average of the last five. In 1946 the number of new entries was the lowest for at least ten years—a reflection of the fall in student entries on the outbreak of war. Last year also the number of graduates from the British Empire overseas coming on to the Colonial List (410) was the highest on record. Only once before, in 1944, has this figure exceeded 300. The number from foreign countries (325) was nearly three times as high in 1947 as in 1946.

The total number of persons on the *Register* at the beginning of the present year was 77,929, being 14,500 higher than the average of the last twenty years. Twenty years ago the number of registered doctors was only about two-thirds of what it is now. The English registrations stand at 36,394, the Scottish at 20,634, the Irish at 10,233, and the Commonwealth at 6,409, this last including 813 "temporaries." The number in the Foreign List is 411, to which must be added 3,748 temporary foreign registrations—persons registered under the Defence Regulations, 1939, or the Polish Resettlement Act, 1947, sect. 5. As from February, 1946, no new registrations have been effected under the Defence Regulations, and sect. 5 of the Polish Act expired on Dec. 31.

The following table gives the position in respect of the *Medical Register* for the last ten years.

	Registered	Restored	Total	Removed owing to death or other reason	Number on <i>Register</i> on Dec. 31
1938	2,365	34	2,399	1,142	61,420
1939	2,968	49	3,017	1,027	63,360*
1940	2,384	37	2,421	1,102	64,679
1941	3,296	16	3,312	996	66,992
1942	3,556	7	3,563	1,127	69,428
1943	3,532	13	3,545	1,091	71,882
1944	2,971	11	2,982	1,218	73,646
1945	2,666	11	2,677	1,190	75,133
1946	2,237	14	2,251	1,092	76,292
1947	2,787	10	2,797	1,160	77,929

\*Figure adjusted in 1940

## The Student Entry

The number of medical students admitted to the schools during the academic year 1947-8 was 2,797. The table of student admissions for recent years is as follows:

1940-1	2,398	1944-5	2,612
1941-2	2,361	1945-6	2,610
1942-3	2,468	1946-7	2,553
1943-4	2,426	1947-8	2,797

## Passes and Rejections

The passes in medicine given by the licensing bodies in the United Kingdom in 1947 numbered 2,594, and the rejections totalled 1,396. In surgery the numbers of passes and rejections were respectively 2,439 and 1,670, and in midwifery 2,631 and 1,460. The English Conjoint Board examined 811 candidates in medicine, 965 in surgery, and 1,060 in midwifery. Next to this the largest numbers were examined by the University of London—726, 628, and 608 in the three subjects. The proportion of passes was highest in Manchester (90.3%), with 72 entries, and lowest in the Scottish Conjoint, being only 49.5% in surgery, with rather fewer than 200 entries.

In the examinations in anatomy and physiology London had the greatest number of entries (820), and the percentage of passes in the two subjects was 79.15 and 72.04 respectively. The percentage of passes in the English Conjoint was 54.7 and 60.8 for 475 and 473 entries. The percentage of passes in physiology in the Scottish and Irish Conjoint was as low as 45. In Cambridge, for an equivalent entry, it was 60.8% and in London 72%.

## The Forthcoming Academic Year

The applications of students for 1948-9 are reported by many of the schools to be well above the number which is regarded as the optimum. The most remarkable figures come from Edinburgh, where 1,400 applications for admission to the

Medical School were received this year, and only just upon 200 could be accepted for the first-year course in October. The Welsh National School of Medicine, which has increased its intake up to the limit of its accommodation, has available places for 60 to 65, and 350 men and women have applied. It must be remembered, of course, that many intending students make application to several schools. St. Bartholomew's Medical College mentions the pressure created by many equally eligible candidates whereby the total will be considerably in excess of the 100 to which it is desired to limit it. At Charing Cross, with an annual admission of 45, priority is given, as elsewhere, to ex-Service students, so that many intending students coming from school are unable to gain entry and have to take their period of national service before beginning professional study. Other London schools report:

St. Thomas's: Eighty admissions into the clinical period, four places in first year reserved for colonial students.

St. George's: Taking the maximum.

Middlesex: Applications from both men and women greatly exceed the number that can be admitted.

At Oxford the number of students is restricted by decree, for the coming year it has been fixed at 65, and ex-Service students are admitted above this number only if born before 1929. At Cambridge the school will again be filled to capacity, but the intake is limited to about 210 by reason of laboratory space. At Birmingham the expected entry is 110, and at Sheffield the limit is 60, which makes selection from many hundreds of applicants difficult. All "firm" applicants at Sheffield are interviewed by a Selection Committee. Sheffield is one of the centres chosen for a long-term investigation into selection methods which is being carried out by Professor Aubrey Lewis and his collaborators under the auspices of the Nuffield Foundation. The investigation is a test of tests, not of individuals.

At Manchester and Liverpool the limitation is to 100 new students per session, but the applications are greatly in excess of this number. At Leeds the expected entry is 75 out of approximately 400 applicants. Bristol takes 60 medical and 25 dental students. The expected entry at St. Andrews is 80, and the same figure obtains at University College Hospital, London. In the University of Dublin the number of students admitted for the study of the basic sciences is limited to 150, and of these not more than 90 will be admitted to the first medical year (anatomy and physiology). It is added that in view of the very large number of applications received there is no reason to doubt that the accommodation will be very fully taxed. At Durham about 60 students are expected to enter the first year, and between 20 and 30 more will be admitted to the second year. At Glasgow the expected entry is 240.

## Selection of Students

On the general subject of student selection, several of the deans mention selection committees. On this we have an interesting note from Professor J. W. Bigger, Dean of the Faculty of Physics, Trinity College, Dublin:

"The pre-medical examination is used as a means of excluding from the Medical School students who do not show promise of completing the course. As this school is situated in Ireland we consider it our primary duty to supply medical education to suitable Irish candidates, whether they reside in the northern or southern part of the island. When their needs have been satisfied the places remaining are allocated to those living elsewhere. Admission to the classes of the pre-medical year is controlled by an admission committee consisting of the Dean, one other representative of the Medical School, and two representatives of the non-medical staff of Trinity College. This committee has complete powers of admitting to, or excluding from, the school. In general the admission committee allocates places to Irish applicants who have become eligible for admission by passing the entrance examination of Trinity College or some other examination recognized as equivalent. The essential subjects include English, mathematics, Latin, and another language. Only when this school or examination record renders it improbable that an Irish candidate would complete the course successfully is he refused admission. When the non-Irish applicants are considered the matter becomes more difficult. There were 775 applicants from outside Ireland for admission to the session 1947-8, of whom only 31 could be admitted.

"The first basis of rejection is non-eligibility because the examinations passed have not included the subjects essential for admission to Trinity College, particularly Latin. The maintenance of compulsory Latin in Trinity College has been a boon to the admission committee.

Even when the non-Latinists are excluded there remain far more applicants than places. At the moment no applicant from the U.S.A. is accepted, because it is believed that if an American fails to get into an American school there must be some good reason for this failure and that it is improbable he would do well with us.

"A quota system has been introduced as regards certain other countries so as to prevent the admission of too high a proportion of students from any one country. There is, for example, keen competition for the limited number of places available for applicants from West Africa. Selection is mainly on the basis of examination record and personal recommendation of teachers and others in a position to judge the potentialities of the applicants. There remain the large number of applicants from Great Britain. They, in common with all applicants, must submit a form of application, giving personal particulars, education record, etc., and supply a photograph. The competition for places among this group is so keen that the primary basis of selection is examination record. Preference is given to men rather than women because of the already high proportion of women in the school, to those with good Service records, to children of doctors, and to those recommended by our own graduates or other persons on whose opinion we rely. Finally, some attention is given to the photograph. We believe that a candidate who looks alert, clean, and carefully dressed is more likely to succeed than one displaying other characteristics. We do not interview any applicants. We are not convinced that a necessarily short interview is of more value than the examination record and a personal recommendation.

### Women Students

The Royal Free Hospital School of Medicine for Women, which was originally entirely a women's school, has had its first session as a co-educational one, and is slightly increasing its number of men students this year. The number of accepted students in 1948 is 87, being 74 for the first medical course, 11 for the second, and 2 for the clinical course, and 78 of the 87 are women. The students at present in the school number 461 women and 2 men. Here again the Interviewing Committee give special consideration to ex-Service men and women. The Royal Free Hospital group now consists of the hospital and its annexe, the former London Fever Hospital in Liverpool Road, the Elizabeth Garrett Anderson Hospital, the Hampstead General Hospital, the Hampstead Children's Hospital, and the North-Western Fever Hospital.

At University College Hospital, with a total entry of 70 or 80, the number of women admitted in the future will be 14 instead of 12. At Charing Cross 20% of the vacancies are allocated to women, at St Mary's about 15%, at St Thomas's the same.

At Oxford, of the 65 entries for the coming year 10 will be reserved for women. Manchester, Liverpool, and Bristol allocate to women one fourth of the total places. At Sheffield all facilities in the Medical School are open to men and women alike, but the number of women entrants is subject to some limitation. In general, from 12 to 15 are admitted, the proportion during the war years was naturally somewhat larger. St Andrews accepts women up to approximately one-third of the total. In the University of Dublin no restriction has up to the present been enforced in the case of Irish women students, but, in view of the high proportion of women students in the school, men applicants from outside Ireland are given preference over women applicants from outside Ireland. Women students have equal eligibility in all faculties of the University of Wales. At Aberdeen 25% of the entrants are women. At Westminster Hospital, London, women clinical students entered the school last April for the first time in many years. Competition for entry among women candidates is exceptionally keen, and it is hoped to increase the numbers admitted. About 40 women students are taken annually at Glasgow. In the University of Durham vacancies allotted to women are about one in four.

### The Curriculum

Those responsible for the school curriculum deserve a certain amount of sympathy in view of the proposals for reform which have been showered upon them during recent years. They had hardly digested the report of the Goodenough Committee and the recommendations of the General Medical Council when they had presented to them the report of the Medical Curriculum Committee of the British Medical Association.\* The Dean of one Irish school writes, perhaps with a touch of exaspera-

tion, that in view of the long consideration given to the two earlier reports it is improbable that his committee will devote much time to the third. Nevertheless the third does present many new points of view. The Dean of St Bartholomew's writes that those parts of the B.M.A. report which affect the College as distinct from the University have been noted with interest, but so many of the suggestions made—as for example in the matter of selecting students—have already been the practice of the College for a considerable time that no specific action is contemplated. The Royal Free Hospital Medical School states that the report has not as yet been considered by any committee, but is being studied with great interest by members of the staff. At Manchester the report has been passed by the Curriculum Committee to the Faculty. At Liverpool a special committee of the Faculty has it under consideration. At Birmingham consideration has been given to the report and as a consequence the Faculty of Medicine has appointed a committee to review the whole of the curriculum. At Bristol it will be considered at the next meeting of the Medical Board.

Certain innovations in the curriculum are reported from various quarters. At University College Hospital, London, a period of senior medical clerkship is planned to take place shortly before the Final. At the London Hospital Medical College a tutorial system providing small groups of students with a first assistant tutor throughout the whole of their clinical course is proving exceptionally valuable. An introductory course designed to help students in the transition from pre-clinical to clinical studies continues to prove highly successful, and liaison with the near-by hospitals for midwifery has added to the number of beds available for teaching in this subject. At St Mary's Hospital the introductory course for the new clinical students has been widened to include the introduction of a number of special subjects.

At Liverpool innovations in the curriculum include the allocation of specific periods of time during clerkship and dressing for instruction in the administration of anaesthetics and for clinical pathology. At Bristol an introductory clinical course has been arranged to bridge the gap between pre-clinical and clinical studies. At Birmingham some modifications are to be made in the early part of the clinical curriculum. On completion of the introductory course students will in future be directed to medical clerkship or surgical dressing instead of, as at present, spending two of the three months of the long vacation attending a series of demonstrations designed to familiarize them with the broad outline of the activities of certain hospital departments.

In the Welsh National School of Medicine steps are being taken to revoke the requirement that candidates for degrees in medicine shall be graduates in arts or science and to adjust the curriculum accordingly. It is still desired that students should be encouraged to read for an honours degree in science before pursuing their clinical studies, but as this would involve at least another year's work it should not be obligatory. At Sheffield a further step has been taken in the transition from the old curriculum to the new. An introductory clinical course will be held in the April-June term for those who have passed the second M.B. in March, *ad hoc* arrangements have been made to meet the needs of students who fail in the second M.B., and also of the small but important group reading for the combined degrees of M.B., Ch.B., and B.Sc.(Hons). All students before qualification have held resident appointments in medicine, surgery, midwifery, and paediatrics.

At Edinburgh from October next the course for the M.B., Ch.B., previously five years, will be extended to six. One difference is that the whole subject of anatomy will not be dealt with in the first-year course. The arrangement of the later years of the curriculum is still under consideration. At St Andrews also a six-year curriculum with implementation so far as possible of the recommendations of the Goodenough Committee has been introduced. Short-term developments at St Andrews include the appointment of whole-time clinical lecturers. At Aberdeen it is proposed to start in October a six-academic-year course, the first year to be spent on the pre-medical subjects of chemistry, physics, and biology. The rest of the course will follow closely that recommended by the General Medical Council and repeated in the report of the B.M.A. Committee. The only new development will be the establishment of a Chair of Biological Chemistry in the Faculties

\*The Training of a Doctor. London: Butterworth and Co (Publishers) Ltd. 7s 6d.

of Medicine and Science, and it is hoped that the first occupant of the chair will take up his duties at the beginning of the winter term. The curriculum at Glasgow is to be revised for 1949-50. In the University of Durham a change has been made in the second M.B., B.S. examination. Part I, held in March and after five terms' work, will consist of physiology only, and Part II, held in June, after six terms' work, will consist of anatomy, pharmacology, and pharmacy. The regulation will take effect from March next.

In the School of Physic of Trinity College, Dublin, the complete course extends to six years, made up of one year of pre-medical and five years of medical study. It is hoped in Dublin in the near future to establish a department of social medicine, but this cannot be done until accommodation for the department is available in the Moyné Institute of Preventive Medicine, which it is hoped will be ready for occupation in 1951.

A revised curriculum introduced last year at Westminster Hospital Medical School has proved its worth, and further changes are being considered. As a result of the new Act the school becomes autonomous, but its links with its parent hospital will be strengthened rather than weakened under the new system. Plans for expansion have been proposed, since existing resources for teaching pathology will soon be severely taxed. There are already enough beds for the clinical instruction of the present numbers. It is hoped eventually to create a 1,000-bed teaching centre in the area bounded by St John's Gardens and Vincent Square, which are five minutes walk apart. A pre-clinical school for 150 students is contemplated. Valuable experience of emergency cases is expected from closer integration with St Stephen's Hospital, Fulham. Closer linkage with child-welfare centres in the district will ensure that students obtain instruction not only in children's diseases but in child health as a whole. The number of undergraduate students at Westminster is rapidly increasing and will reach 165 by next April.

#### The Older Universities

All students entering the Medical School at Oxford in future will be required to take the second public examination as before the war. The course normally adopted to satisfy this regulation is that of the Final Honour School of Animal Physiology, which takes up one year after passing the anatomy and physiology examination for the B.M. degree. The newly established clinical school allows students to qualify at Radcliffe as an alternative to transfer to a teaching hospital elsewhere. A students club has been opened in Osler House, offering social facilities and sleeping accommodation for those on duty at the hospital. This social, administrative, and teaching centre will be completed by a lecture-room and a class-room which are soon to be constructed in an adjoining building.

It should be noted that at Oxford the various colleges put forward the names of students whom they wish to be admitted to the Medical School, and preliminary acceptance by a college is essential for any prospective medical student. Each of the colleges, whether for men or women, has a 'society,' and there is one non-collegiate society on each side. All inquiries should be addressed to the head of the society—principal, president, master, rector, as the case may be—and not to the secretary of the Medical School, and the prospective student is advised to make application well in advance of his or her eighteenth birthday.

At Cambridge it is proposed to establish a school of veterinary medicine, and during the preclinical period medical and veterinary students will work together in the basic subjects which are common to both professions. The post of Professor of Animal Pathology has been revived. If the proposal for a complete veterinary school for Cambridge is accepted, the new venture should be of mutual benefit to both medicine and veterinary medicine. The natural sciences tripos, in which the sciences ancillary to medicine are considered from a wider and more disinterested point of view and the student is allowed to interpret his study on larger lines—always the great and abiding advantage which Cambridge offers—will include instruction by the Professor of Animal Pathology. The first step has been taken towards a university department of paediatrics by the appointment of a paediatrician to the staff of Addenbrooke's. A department of human oecology has been set up, with the appointment of a reader. The University Health Service, under which prophylactic examinations, including mass radiography,

will be carried out, will be ready to work to full capacity on the new intake in October.

#### Developments in London Undergraduate Schools

Long-term developments at certain London schools still concern rebuilding to make good war damage. Middlesex Hospital during the past year has completed its reconstruction, every bed is now in use, and students have the advantage of attending the wards and out-patient departments of the Central Middlesex Hospital, Willesden. Middlesex has made an arrangement with the North-Eastern Fever Hospital by which its students are resident for three weeks. An overall plan has been approved at St Bartholomew's for the whole preclinical unit, and opportunity has been taken to incorporate resident quarters while replacing pre-existing departments. At University College Hospital the short-term development plan consists of the addition of some 300 beds by the taking over of St Pancras Hospital. These include wards for the chronic sick, a modern obstetric block, and mental observation wards. The Hospital for Tropical Diseases is now part of University College Hospital, and will continue to provide clinical material for postgraduate teaching.

At Charing Cross the reopening of the anatomy and physiology departments last October has proved of great value. The students have successfully completed the first part of the course leading to the second M.B. examination, which will take place next March. The facilities of the hospital and school are reserved for the full-time undergraduates, and no courses for postgraduates are provided. As a result of the National Health Service Act the school is now separately incorporated from the hospital, but the close association between the two parts of the institution will be preserved by the interchange of members between the controlling authorities—namely, the School Council and the Board of Governors of the hospital. Planning for the new medical centre at Harrow continues to make good progress. A hospital will be erected there to accommodate 1,000 patients and a school with an annual entry of 100 medical and 50 dental students.

The London Hospital has increased its beds during the year to just upon 700. The redecoration of the Medical College, with complete renovation of the museum, and a new bacteriological department in the hospital have provided additional facilities for medical students. An annexe of 208 beds is still maintained at Brentwood, where students attend special courses and demonstrations, particularly in tuberculous disease of the chest.

At King's College Hospital Medical School, which provides the clinical instruction for students reading for the medical degrees of Oxford, Cambridge, and London, the present session has seen the establishment of two university chairs in the department of pathology—a chair of morbid anatomy and a chair of chemical pathology. A sub-department of bacteriology has also been established. The Borland Scholarship for Women, value £500, has been founded, and will be awarded for the first time in 1949. A Wiltshire Memorial Research Scholarship and a Legg Memorial-Lecture have been established to commemorate two former members of the staff of the hospital and school. As from July 5 the school became incorporated under its own charter, and a new Academic Board will aid the Dean and the directors of clinical studies in effecting a gradual modification of the curriculum to bring it into line with the latest recommendations of the Goodenough and the B.M.A. reports. In view of the impossibility of enlarging the hospital for some years to come, arrangements have been made for the use of medical beds for teaching purposes in a near-by regional hospital. Plans have, however, been made to enlarge the Medical Research Council's dental research unit. It should be added that the preclinical studies are taken at King's College, Strand, and applicants are interviewed jointly by a committee representing the College and the Medical School. This committee includes a layman and a non-medical member of the teaching staff.

#### Schools Outside London

The main development at Bristol during the year has been the provision of studies and laboratories for the two whole time clinical departments of medicine and surgery in the building of the Royal Hospital and adjacent to the respective wards. At Sheffield plans have been produced for the rebuilding both

of the Medical School and of the teaching hospitals, but it is still impossible to say when a start will be made. It is expected that Sheffield, with the sympathy of the city and other bodies concerned, will establish a whole-time chair of social and industrial medicine in the near future. Co-operation between city and university in another sphere has resulted in the establishment of a university department of forensic medicine, under the charge of Dr Gilbert Forbes police surgeon to the city with the title of part-time senior lecturer. The establishment of full-time chairs of obstetrics and gynaecology and of psychiatry is in contemplation. Developments in the hospital sphere of interest in Sheffield, though not directly concerning the university, include the appointment of a clinical artist, the establishment of a department of medical photography, and the intended opening during the next year of a school of physiotherapy.

At Birmingham, where the difficulties caused by doubling the entry of students have proved formidable, considerable progress has nevertheless been made with the new developments in the Medical School. A second chair of anatomy has been created and a further innovation has been made by the appointment of two professors of pathology—one in experimental pathology and the other in morbid anatomy. The first chair of anatomy and the chairs of physiology and medicine have been named after former distinguished members of the Medical School—Sands Cox, Bowman, and William Withering respectively. Following the practice of the older universities, whereby an outstanding individual is elected to a chair specially created for him, part-time professorships have been created in therapeutics and gastroenterology, the latter the only one of its kind in the British Isles.

The regulations for higher degrees (M.D. and Ch.M.) at Birmingham have been amended, and the main emphasis will in future be on a thesis based either on original research or on the application of scientific methods to medicine or surgery. The regulations for the award of the M.D. degree in State medicine have been withdrawn and the degree abolished. The regulations for the degree of Ph.D. of the Faculty of Medicine have also been amended. Lectureships in operative surgery, vaccination, and applied anatomy have been abolished. The course in the last subject is to be under the direction of the department of anatomy in collaboration with the head of the clinical departments.

Under the National Health Act a 'teaching hospital' has been formed in Birmingham and includes the names of those hospitals at which the teaching of dentistry and the four major subjects of the curriculum has up to now been carried out. This 'teaching hospital' will be administered by a board of governors, on which there will be a strong university representation.

In the Welsh National School of Medicine the inclusion in the teaching group at Cardiff of the former municipal hospital at Llandough will help so far as the clinical period is concerned. As a long term policy, plans are being prepared for a 1,000 bed teaching hospital together with a new medical school.

## POSTGRADUATE TRAINING FACILITIES

### THE LONDON SCHOOL AND INSTITUTES

The British Postgraduate Medical Federation, to whose Director, Sir Francis Fraser, we are indebted for up-to-date information, is now a school of the University of London, and the Postgraduate Medical School at Hammersmith and the Institute of Psychiatry have been recognized by the University as federated institutes. A number of the other institutes in London await inspection by the Senate before they also receive similar status. All the institutes now provide clinical instruction of a high standard, though some of them, owing to lack of accommodation, are unable as yet to provide the facilities for research necessary for them to give education of advanced university level.

Last year advantage was taken of clinical facilities at certain municipal hospitals. This arrangement has now ceased, but the Central Office of the Federation hopes to make direct use not only of these hospitals but also of many others under the Regional Boards for the postgraduate education both of specialists and of general practitioners. For this purpose a

Regional Adviser in postgraduate medical education is being appointed by the Federation, on behalf of the University, to each of the four metropolitan regions. Three of these posts have already been filled, no appointment has yet been made to the north-western region.

The duties of these regional advisers will be to carry out the policy of the University and the Federation in arranging postgraduate education, to act as liaison between practitioners in the region, the medical schools and teaching hospitals, the regional board, and the hospital management committees, to assist the undergraduate schools in finding for their graduates suitable house-officer appointments in non-teaching hospitals, to assist all medical schools in finding for postgraduates suitable appointments in non-teaching hospitals, and to arrange for general practitioners and public health officers of the region clinical assistantships in near-by hospital centres, regular clinical meetings, short courses, and longer or more intensive general refresher courses.

It is planned, by the way, to organize refresher courses on the same lines as in the past for general practitioners. Financial assistance was given to insurance practitioners on certain conditions in respect of their attendance at specially arranged courses. The Ministry of Health is now drawing up regulations which are expected to include grants for National Health Service practitioners. The Act provides that the Minister may enter into arrangements with universities and schools for the provision of courses which practitioners may attend and may make payments towards the cost of providing such courses and the expenses of practitioners attending them.

The Federation and the three Royal Colleges in London have set up a joint board to effect co-operation in providing for postgraduates and to prevent overlapping. Sir John Anderson has agreed to be chairman, and the board will consist of two representatives of each of the Royal Colleges and of the governing body of the Federation. Among the matters to which the joint board will give its attention will be

- (1) Provision of advanced courses in the basic sciences
- (2) Opportunities for intending specialists to supplement responsible hospital appointments and practical clinical work by courses of lectures and demonstrations, etc.
- (3) Access to clinical material for those attending lectures and demonstrations
- (4) Revision courses for established specialists
- (5) Postgraduate training in special subjects for graduates other than those intending to specialize in those subjects
- (6) Co-ordination of lecture provision
- (7) Procedure for enabling selected graduates from overseas to obtain suitable hospital appointments
- (8) Expert advice and guidance for graduates seeking education and training in the specialties

The address of the Federation is 2, Gordon Square, W.C.1

### The Hammersmith School

For the following notes on the Postgraduate Medical School, Ducane Road, Shepherd's Bush, which is an institute of the Federation and has been a school of the University of London since its inception in 1935, we are indebted to Dr Charles Newman, the Dean.

The teaching in the clinical departments consists of bedside teaching, reinforced with lectures, clinico-pathological conferences, radiological and post-mortem demonstrations, and attendance at operations. The full programme of organized teaching is carried on in ten-week periods, corresponding to the University of London terms. During the vacations the staff is engaged in research work and the higher education of selected students, but organized teaching ceases, and other arrangements are made for those students who are not selected to remain at the school. Short-term students desiring two or more terms of concentrated instruction are therefore advised to book in October or January so as to avoid including the long vacation in their stay. House appointments are usually made from among students, and facilities are provided for senior students who wish to carry out original research under the Director.

About 60 students can be accommodated in the department of medicine, and resident appointments are available for about 20. A similar number can also be accommodated in the department of surgery, which provides training for general surgeons but instruction in orthopaedics, otolaryngology, and urology is included. Teaching is so organized as to be continued from

out patient departments through the wards and operating theatres to follow-up clinics. Students do not themselves perform operations. There are at present no facilities for work in preparation for the primary FRCS examination.

The department of obstetrics and gynaecology is now joined with the combined school of Queen Charlotte's and Chelsea Hospitals to form a provisional Institute of Obstetrics and Gynaecology. It is therefore able to provide students with an increase in teaching facilities. The department at the Postgraduate School provides teaching in the antenatal and post-natal clinics and in the sterility clinic, as well as in the wards and operating theatres, and, in addition, lectures and conferences in term time. The department at Queen Charlotte's provides full scope for teaching in obstetrics, and the department at Chelsea provides more extensive teaching in gynaecology and gynaecological endocrinology than has hitherto been possible at this school.

The department of pathology is organized in four main sections: (1) morbid anatomy and histology, (2) bacteriology, (3) haematology and clinical pathology, and (4) biochemistry, and instruction is adapted to the requirements of the course for the diploma in clinical pathology of the University of London. The course lasts for one year, starting in October. There are twenty places available in this course, and selection from them is made in June. Fortnightly and six-monthly courses in practical anaesthetics are also given. In the department of radiology teaching is based on the requirements for the diploma in medical radiology.

### The Specialist Institutes

The Institute of Cardiology (National Heart Hospital, Westminster, W1)—Six appointments of registrar type are available per annum for physicians in training as cardiologists. Training includes clinical cardiology, radiology of the heart, electrocardiography, and research. General physicians may enrol for full- or part-time instruction for one term of approximately three months. There are three terms annually, starting in January, May, and October.

The Institute of Child Health (Hospital for Sick Children, Great Ormond Street, WC1, and Hammersmith Hospital)—Teaching in every aspect of child health is provided, including instruction on the newborn and premature infant. Three terms each of three months' duration, starting in January, May and September.

The Institute of Dermatology (St John's Hospital for Diseases of the Skin)—Clinical teaching in out-patient department twice daily, also facilities for study and tuition in the pathological laboratory.

The Institute of Diseases of the Chest (Brompton Hospital)—Teaching primarily by means of hospital practice, students enrolling for three months or more in approximately a half-time course of instruction.

The Institute of Laryngology and Otology (Royal National Throat, Nose, and Ear Hospital, Gray's Inn Road, and Golden Square, WC1)—A comprehensive full-time course lasting 20 weeks and designed to cover the whole field of the specialty is held twice a year, starting in January and July. A part-time advanced revision course, lasting for ten to twelve weeks, suitable for students preparing for the higher qualifications, is held twice yearly approximately from February to May and from September to November.

The Institute of Neurology (National Hospital for Nervous Diseases, Queen Square, WC1)—The teaching is mainly by attendance on the hospital practice, and there are three terms annually. More advanced students are appointed as clinical clerks in the wards or attached to special departments and the research laboratories. In addition to this, two ten-weeks courses, which are whole-time, are held in the autumn and spring terms.

The Institute of Ophthalmology (Moorfields, Westminster, and Central Eye Hospitals)—In addition to the teaching by means of hospital practice, a routine lecture and tutorial course lasting four or five months, is held twice a year, beginning in March and October. Part I consists of anatomy, embryology, histology, physiology, optics, and elementary clinical instruction. Part II comprises bacteriology, pathology, operative surgery, medical ophthalmology, and all aspects of ophthalmic disease.

The Institute of Orthopaedics (Royal National Orthopaedic Hospital, Great Portland Street, W1)—The practice of both the central hospital and the country branch at Stanmore is open to postgraduate students. In addition to the hospital practice a comprehensive basic course of six months' duration consisting of lectures and demonstrations begins in October.

The Institute of Psychiatry (Maudsley Hospital, Denmark Hill, SE 5)—Training normally covers a period of two to three years after adequate experience elsewhere in general medicine, and is based on responsible hospital duties under supervision. Regular series of lectures and demonstrations by experts in various fields relevant to psychiatry are given throughout each of the university terms.

The Institute of Urology (St Peter's and St Paul's Hospitals, Henrietta Street, WC2)—Three courses of fourteen weeks' duration are held annually, beginning in January, April, and September. These include systematic lectures covering the whole subject of urology, out-patient sessions, ward visits, operation sessions, and tutorial demonstrations.

An Institute of Dental Surgery, a dental counterpart to the Institutes of Child Health, etc., has just been set up at the Eastman Clinic. As already noted, an Institute of Obstetrics and Gynaecology is now being formed, combining the department at the Postgraduate Medical School and the combined School of Queen Charlotte's and Chelsea Hospitals. It will start work as an Institute next month.

### Facilities in Other University Centres

The following is a not exhaustive list of courses of postgraduate instruction held regularly at universities other than London. All are full-time courses except those of neurology at Birmingham, psychiatry at Manchester and the 12 months course for the DPH in the University of Wales which are part-time.

Subject	University	Duration	Starts
Anaesthetics	Bristol	2 weeks	April and Oct
	Oxford	2 "	Mar and Sept
Bacteriology	Manchester	9 months	Oct
Industrial health	Birmingham	4 weeks	Each univ term
	Edinburgh	9 months	Oct
	Glasgow	9 "	
	Manchester	9 "	
Medicine (general)	Edinburgh	12 weeks	April and Oct
	Glasgow	8 "	
Neurology	Birmingham	2 months	Continuous during univ terms
Obstetrics and gynaecology	Glasgow	3 weeks	May and Nov
Ophthalmology	Birmingham	6 months	Jan and July

### Other Postgraduate Arrangements

The West London Hospital Medical School which during the past eleven years has accepted undergraduate students for the clinical part of the medical curriculum, is now, after

prolonged negotiation with the University of London, shortly to join the British Postgraduate Federation, in which its future work will be the training of specialists in general medicine and general surgery. With this in view the hospital has been grouped with the Hammersmith and St Mark's Hospitals as one of the designated teaching hospitals under the National Health Service Act. For the time being the West London Hospital Medical School and the British Postgraduate Medical School will operate independently, but the West London will not accept any undergraduate students after October. So far as can be foreseen, it will be possible to admit a small number of postgraduate students in the summer of 1949 and to replace an undergraduate by a postgraduate community entirely by 1952.

At Cambridge the School of Postgraduate Teaching and Clinical Research is well on its way. A successful innovation has been the establishment of trainee posts in the clinical pathology department of Addenbrooke's Hospital. These posts which carry a "living wage," offer two years' training in all aspects of clinical pathology, post-mortem work, histology, and chemical pathology.

Postgraduate teaching in the University of Liverpool offers full-time courses for the degrees of Ch M, M Ch Orth, and M Rad, granted by the University, and for the diplomas of D P H and D T M & H, the latter in conjunction with the Liverpool School of Tropical Medicine. These courses are also suitable for candidates studying for the F R C S and D M R E examinations. There is a new full time course in anaesthesia lasting one year, commencing in October, and a course throughout the academic year for postgraduate students proceeding to the degree of M D, which is usually attended by candidates for the M R C P. A part-time course of obstetrics and gynaecology is held throughout the academic year, beginning in October, and a short intensive course in paediatrics lasting three weeks and suitable for candidates studying for the Diploma in Child Health is held once or twice a year. The course in radio-diagnosis lasts two years, not eighteen months as formerly.

At Leeds a feature of postgraduate work is weekly clinical meetings for general practitioners and clinical week-ends at intervals on special subjects. A 14 days refresher course for general practitioners is planned. A postgraduate committee is in charge of these activities and of the Ministry of Health scheme for demobilized medical officers. Middlesex Hospital, London, holds one course a year for the primary Fellowship examination of the Royal College of Surgeons. It also provides special courses for graduates for the diplomas in medical radiology, both diagnostic and therapeutic.

The Faculty of Radiologists (45, Lincoln's Inn Fields, WC 2) offers a Fellowship (F F R) to medical graduates of five years' standing who have spent at least one year in general clinical work at an approved hospital, hold a radiological diploma, and have practised radiology exclusively for at least two years subsequent to obtaining that diploma. Candidates are required to pass an examination and submit a thesis. Those holding higher qualifications may be exempted from examinations in general medicine, surgery, or pathology. Full particulars may be obtained from the Warden.

Apart from London, Edinburgh has probably more postgraduate courses than any other centre. These include general medicine and surgery, industrial health, psychiatry, etc. Particulars from the Director, Postgraduate Board for Medicine, Edinburgh. In Dublin, with the co-operation of the ten teaching hospitals, the Royal College of Surgeons in Ireland has arranged a postgraduate course in surgery.

### The Royal Colleges

The Royal College of Physicians of London holds a series of lectures for postgraduates on advanced clinical subjects. The lecturers are specially distinguished in their respective fields, and are drawn from the provinces as well as London. The audience for these lectures, which are given four times a week and will be continued apart from vacations, is limited to 200. A short full time intensive course in paediatrics is also given. Details can be obtained from the Registrar of the Royal College, Pall Mall East, SW 1.

The Royal College of Surgeons of England (Lincoln's Inn Fields, WC 2) has instituted a number of postgraduate courses in various subjects—surgery, anaesthetics, dental surgery and

anatomy, applied physiology, and pathology. The programme of lectures on general, oral, and dental surgery includes 34 during the month of September alone. Lectures on surgery to be delivered at the College during October number 12, each by a different lecturer. In the same month 45 lectures on anaesthetics are to be given—three daily—and a series of tutorials in anaesthetics will be held during the same period. From October to December 72 lectures in anatomy, applied physiology, pathology, and pharmacology have been arranged. From January, 1949, there will be residential accommodation available within the College for postgraduate students. Many lectures are also given at the other Royal Colleges and Corporations.

The Royal Cancer Hospital (Free) (Fulham Road, SW 3) offers facilities to postgraduates for the study of cancer. Courses of instruction extending over a period of two years are given for candidates preparing for the diploma in medical radiology. In addition short courses of instruction are given in radiotherapy extending over periods from two weeks to two months. Facilities are offered to postgraduates to attend the out-patient department, wards, and operation theatres, courses of lectures in the diagnosis and treatment of cancer are also arranged. Appointments as honorary clinical assistant are available for suitable candidates. Courses of instruction are given in clinical and operative surgery for postgraduates preparing for the final F R C S examination. The department of pathology participates in this course and also in the course of the D M R examinations, and individual postgraduates are accepted, when possible, for special tuition and research work. The Chester Beatty Research Institute is exclusively devoted to experimental investigations on cancer, and facilities are provided for suitably qualified workers studying for a higher degree.

At Middlesex Hospital special courses are provided for graduates for the diplomas in medical radiology, both diagnostic and therapeutic. One course a year is held for the primary F R C S examination.

For many years the Fellowship of Postgraduate Medicine (1, Wimpole Street, W 1) has administered a bureau providing general information on postgraduate work and arranging courses of instruction at hospitals. Practitioners from overseas visiting London can be advised as to postgraduate facilities by the Empire Medical Advisory Bureau, recently set up by the B M A at Tavistock Square.

## ENTRANCE INTO MEDICAL TRAINING

### Students' Registration

Every candidate for registration as a medical student must, by regulation of the General Medical Council, produce evidence that he has attained the age of 17 and has passed an approved examination in general education and, in addition, an examination in elementary physics or chemistry conducted or recognized by one of the licensing bodies. He is required to have passed in English, a language other than English, elementary mathematics, and an additional subject or subjects, such as history, geography, physical science, natural science, and Latin or some other language recognized by the university for the purpose. Subject to this condition, the General Medical Council recognizes responses of Oxford University, the previous examination of Cambridge, the matriculation examinations of other universities of England and Wales, and the equivalent examinations of the Scottish and Irish universities, also all examinations accepted by one or more of the universities or other bodies as equivalent, for the purpose of entrance or matriculation, to their own. These include the school and higher school certificate examinations of the Oxford Delegacy for local examinations, the Cambridge local examinations, the examinations of other universities, and the leaving certificate examination of the Scottish Education Department. The examinations of Colonial universities which are similarly accepted by one or more British universities for the purpose of matriculation will also be recognized. The final examinations for degrees in art and science of any home or Dominion university are also recognized.

### Deferral

The Ministry of Labour and National Service has directed that preference for admission to medical schools should be

given to those who have served in the armed Forces or have been engaged in approved war work. By regulation deferment is granted only to male students born between Oct 1, 1929, and July 31, 1930 (both dates inclusive), who have been selected by the joint recruiting board of the appropriate university. Joint recruiting boards will be unable to consider applications from men in this age group who intend to enter the university after October, 1948. The above statement is made on the assumption that the regulations of the Ministry of Labour will remain the same as those for students in the previous age group—that is, Oct 1, 1928, to Sept 30, 1929.

Any male student born between Aug 1, 1930, and July 31, 1931, who at the time of his registration under the National Health Service Acts is in residence at a university or has been provisionally accepted for admission, should apply to the appropriate joint recruiting board for provisional deferment as soon as possible after registration. If he is granted deferment he will be called up on completion of his course, when he will serve in a medical capacity. Applications for deferment have to be made in duplicate to the secretary of the University Joint Recruiting Board on Form Misc 20, to be obtained from the school, and forwarded by the date fixed by the Ministry of Labour.

### The Student at Oxford

It may be useful to follow the course of a student at Oxford. To attend the course he must be a member of the University, and for this purpose he must be accepted by one of the collegiate or non-collegiate societies already referred to (p 486) and must pass or be exempted from the University entrance examinations, responses, in which Latin is normally compulsory. There is, however, some relaxation of the responses requirements for those who have spent not less than six months on approved war service. Owing to the limited number of places in the Medical School a prospective student, after he has been accepted as a candidate for admission by a college, must be considered and accepted by the University committee set up to select the students who are to make up the quota of 65 for the given year.

After having got over this hurdle he is eligible to go into residence and is qualified for admission into the Medical School, and therefore for deferment of military service—subject to satisfactory periodical reports on his progress—by the joint recruiting board. Before beginning work for the first BM examination, however, he must pass certain preliminary examinations in natural science—subject 4 (biology), or subject 3 (chemistry), or subject 5 (physics and chemistry). These preliminary examinations can be taken either from school or after the student has gone into residence at Oxford.

The subjects for the first BM are organic chemistry, human anatomy, biochemistry, and physiology. The course in the first of these is open to students who have passed the preliminary examinations in physics and chemistry—in other words, it can be pursued by those who still have to pass biology. About two clear years are required for the study of human anatomy, biochemistry, and physiology, and the student must pass these subjects simultaneously in the examination at the end of the course. By statute no one can take the BM, BCh degree unless he has first taken a BA degree, the course usually chosen for this being the Final Honour School of Animal Physiology. Candidates who take subject 5 (physics and chemistry) as one of the preliminary examinations for admission to the Final Honour School of Animal Physiology must reach the higher standard in both physics and chemistry.

The student next prepares for the second BM, in which the subjects are pharmacology and principles of therapeutics, general pathology and bacteriology, forensic medicine and public health, special and clinical pathology, medicine, surgery, and midwifery. Most students, even those not intending to do their clinical work at Oxford, find it convenient to take the courses in general pathology and bacteriology, and pharmacology and principles of therapeutics, at the University. Students who carry out their clinical work at Oxford must complete the courses in these subjects before entering the clinical school at Radcliffe Infirmary. The clinical course extends over a period of approximately thirty-three months. Unless a candidate is already a registered medical practitioner the examination in medicine, surgery, and midwifery cannot

usually be taken until the eighteenth term from university matriculation.

All the universities, following the results of examination, confer qualifying bachelor degrees in medicine and surgery. The abbreviations are BM, BCh Oxford, MB, BChir, Cambridge, MB, BS, Durham and London, MB, ChB, other English and Scottish universities, MB, BCh, University of Wales, Queen's University, Belfast, and National University of Ireland. The baccalaureate in medicine and surgery and the licence in medicine and surgery of the University of Durham both admit primarily to the *Register*.

### The English Conjoint

The qualifying diplomas LRCP Lond, MRCS Eng were taken by about one fifth of those who qualified last year. Candidates are examined by the Examining Board in England of the Royal Colleges (Examination Hall, Queen Square, WC 1). Three examinations have to be passed: a pre-medical examination, a first examination in anatomy, physiology, pharmacology, and materia medica, and a final examination in pathology and bacteriology, medicine, surgery, midwifery, and gynaecology. Candidates are required to complete the medical curriculum extending over not less than fifty-four months of study at recognized medical schools and hospitals, and to pass the professional examinations in accordance with the regulations after passing any two parts of the pre-medical examination. The Board does not itself conduct the preliminary examination in general education but recognizes a number of matriculation examinations and school-leaving certificates.

The examinations of the Board are conducted four times a year, and candidates are required to give notice to the secretary of the Board twenty-one days before the examination. The first medical examination is in two parts: (1) anatomy and physiology, written, oral, and practical, and (2) pharmacology and materia medica, oral only. In the final examination, medicine, surgery, and midwifery and gynaecology are written, clinical, practical, and oral, pathology is written and oral only, and may not be taken alone as the last part of the examination. Candidates who produce evidence of not less than twenty-four months recognized clinical study subsequent to passing in anatomy and physiology are admissible to any one part only of the examination, on the completion of twenty-seven months study they are admissible to one or two further parts, or to three parts if presenting themselves for the first time. Candidates may not enter for the first part of the examination until they have completed thirty months' clinical study.

Before admission to the final examination candidates must show that they are at least 21 years of age and must produce evidence (1) of having attended certain specified courses at a recognized medical school and hospital, (2) of general out-patient and in-patient attendance at a hospital during thirty months, six months' medical clinical clerkship, six months' surgical dressership, and three months' gynaecological clerkship, (3) of attendance at five labours by a teacher or member of the staff of an approved hospital and of having subsequently conducted fifteen other labours, (4) of having received instruction in children's diseases and the care of infants, and in the eye, throat, nose, and ear, and skin departments of general hospitals or at special hospitals, and (5) of having received instruction in venereal diseases, radiology, and vaccination, and of having attended courses, including clinical demonstrations, at a fever and at a mental hospital.

### The Scottish and the Irish Conjoint

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have made arrangements by which, after one series of examinations, held in Edinburgh or in Glasgow or in both Universities, students may obtain diplomas of the three co-operating bodies (LRCP, LRCS Ed, LRFP & SGlas). Each of these corporations grants its single diploma after examination but the single diploma does not confer the right to qualifying registration, it is only a qualification additional to those already on the *Register*. The course of professional study embraces a certified period of not less than five academic years in the last three of which clinical subjects must be studied. The first examination embraces physics, chemistry, and biology, the

## LIVER *at meal times*

## *In a Palatable, Readily Acceptable Form.*

Proteolysed Liver A & H is prepared by a process which eliminates the nauseating flavour of raw liver. Its palatability has been further improved by its presentation in a paste form. It may be readily incorporated in the normal diet by its inclusion in soups or on toast, bread or dry biscuits.

In pernicious anæmia and other megalocytic anæmias, proteolysed liver has proved effective in cases which have failed to respond to extracts of liver in general use.

**A** COLLOID OF FERRIC HYDROXIDE (10% Fe) One teaspoonful is equivalent, in iron content, to approximately 30 grs iron and ammonium citrate

Neo-Ferrum is an inexpensive and highly effective form of iron suitable for general use in the treatment of iron deficiency anæmias. It is pleasantly flavoured and does not upset the stomach nor discolour the teeth.

Neo-Ferrum Tablets provide an extremely convenient and pleasant alternative, two tablets are equivalent to one teaspoonful of the liquid product.

Neo-Ferrum may be given to young infants as well as to children and adults. The liquid preparation is readily miscible with milk feeds.

second anatomy and embryology and physiology, biochemistry and biophysics, the third pathology, materia medica, and pharmacology. The final examination consists of two parts: the first part forensic medicine and public health and the second part medicine, surgery and obstetrics and gynaecology. All candidates at the final examination must also produce certificates of efficiency in the practice of vaccination from a Government teacher in the United Kingdom. Candidates for the Scottish Conjoint may work at any of the medical schools of Great Britain and Ireland. Details may be obtained from the Registrar, 18, Nicolson Street, Edinburgh 8.

The Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland issues a joint licence in medicine, surgery and midwifery (RCP I & L M, RCSI & L M) and accepts candidates from most of the medical schools at home and overseas. Regulations are obtainable from the secretary of the Conjoint Board, Royal College of Surgeons, St. Stephen's Green, Dublin.

#### Other Diplomas

The Society of Apothecaries of London (Apothecaries Hall, Black Friars Lane, EC4) grants the diploma of Licentiate in Medicine and Surgery (L.M.S.S.A. Lond.) to candidates who pass in the primary examination, which is held quarterly, and the final examination, which is held monthly except in September. The minimum period of study is normally five years.

The Apothecaries Hall of Ireland (95 Merrion Square, Dublin) grants L.A.H. Dubl. to those passing the three professional examinations.

Diplomas in medicine and surgery registrable in the Colonial List are those granted by the Universities of Sydney, Queensland, Adelaide and Melbourne, Ceylon Medical College, University of Hong Kong, Royal University of Malta, New South Wales Medical Board, University of New Zealand, Universities of South Africa, Capetown, and the Witwatersrand and the King Edward VII College of Medicine, Singapore. Under certain conditions diplomas of colleges in Canada are registrable, also with some exceptions and subject to future diplomas of the Universities of India and the University of Rangoon.

#### Higher Qualifications

All universities confer on graduates holding a bachelors degree the higher qualification of Doctor of Medicine or Master of Surgery. Durham offers Doctor of Surgery and Liverpool Master of Orthopaedic Surgery (M.Ch.Orth.). The Irish universities offer the degree of Master of Obstetrics (M.A.O.). The requirements of the universities vary, and particulars should be obtained from the one selected. To obtain the D.M. of Oxford a thesis satisfactory to the Board of the Faculty must be presented; the degree of M.Ch. is conferred on the result of an examination.

The Royal College of Physicians of London confers its Membership (M.R.C.P.) by examination. The pass examination for Membership consists of a written examination in the form of a paper on questions of medical anatomy, pathology, principles of medicine, a paper on questions on the practice of medicine, including the principles of public health and on psychological medicine, a clinical examination in the clinical wards of a hospital, and oral examinations.

The Royal College of Surgeons of England grants its Fellowship (F.R.C.S. Eng.) to those who pass its primary and final Fellowship examinations. The primary examination, partly written and partly oral, is held in January and July and the final examination, partly written, partly practical, and partly oral, and including the examination of patients, is held in May and November. Until Jan 1, 1949, candidates for the examination in general surgery may be admitted to the final examination on producing a certificate of not less than six consecutive months in a resident post in charge of general surgical patients in the wards of a recognized general hospital.

#### A Fellowship in Dental Surgery

The 1948 edition of the *Dentists Register* is the first to include the Fellowship in Dental Surgery of the Royal College of Surgeons of England as an additional qualification. Dr. E. W.

Lish, chairman of the Dental Board addressing the Board recently said:

The institution of this Fellowship is a most welcome landmark in the association of the Royal College with dental surgery—an association which first achieved practical expression when the Licence in Dental Surgery was instituted a long ago in 1859. That the Royal College should have decided to award their Fellowship with all the honour and prestige which attaches to that distinction to dental surgeons who are not graduates or diplomates in general medicine provided that they can give evidence of advanced knowledge in anatomy, physiology and pathology as well as in the practice of clinical dentistry, may well prove to have far-reaching effects on dental education.

It is generally agreed that a training in medicine provides a most liberal and valuable background for the practice of dentistry, yet it has been realized for some time that the increasing complexity of the course of study in general medicine coupled with the rapid evolution of dental science and practice had rendered it hardly feasible for a student to achieve the double qualification. No longer the difficult matter of old times is it possible for a post-graduate student to obtain the Fellowship in Dental Surgery of the Royal College of Surgeons by discharging himself in the clinical practice of his own specialty after he has devoted five years to the study of a particular aspect of general and medical science, a matter that practice demands. The medical school and the science school will remain an indispensable part of the education of the student who intends to make a career in the academic world of dentistry or in research, but the clinical practice and research is likely to be more attracted by the course of study for the new Fellowship. In this way he will be pursuing his own specialty while he pursues his studies; the increased knowledge he acquires will be directly related to his clinical work. He will reach his goal in a shorter time and the pressure on the medical school will be appreciably relieved.

For this diploma (F.D.S.R.C.S. Eng.) candidates are required to pass a primary and a final examination.

Membership of the Royal College of Obstetricians and Gynaecologists (M.R.C.O.G.) may be applied for by medical graduates who have been registered or eligible for registration for at least three years. The Fellowship (F.R.C.O.G.) is reserved to members who are considered to have advanced the science and art of obstetrics and gynaecology. The address of the College is 58, Queen Anne Street, W.1.

The Royal College of Physicians of Edinburgh (20 Queen Street, Edinburgh 2) examines for Membership four times a year. Only a person who has been for at least three years a Member can be elected to the Fellowship; every proposal for election to which must be signed by four Fellows.

Changes have been made recently in the laws relating to the Fellowship by examination of the Royal College of Surgeons of Edinburgh (Surgeons Hall, 18 Nicolson Street, Edinburgh). The examination consists of two parts: the first consisting of a written paper and an oral examination in anatomy and physiology and in pathology and bacteriology, and the second consisting of a written paper, a clinical or practical examination, and an oral examination on the principles and practice of surgery and on an optional subject chosen by the candidate from the following: surgical pathology and operative surgery, laryngology, otology and rhinology, obstetrics and gynaecology and ophthalmology.

#### New Fellowship Regulations of Royal Faculty

The Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship *qua* physician and *qua* surgeon and regulations in substitution for the present regulations come into effect on June 1 next.

Candidates for the Fellowship *qua* physician must have been medically qualified for not less than three years and must have been engaged during one of those years in full-time clinical work in a recognized hospital, and have spent two other post-graduate years in medical work approved by the Faculty. The examination consists of written and oral examinations in the principles of medicine and therapeutics and the practice of medicine and medical pathology, and a clinical examination.

For the Fellowship *qua* surgeon candidates must be medically qualified and pass a primary examination and a final. The primary examination comprises written and oral examinations in anatomy and physiology and in pathology and bacteriology. To be admitted to the final examination candidates must have been medically qualified for not less than three years and produce evidence that they have been engaged since qualification for a period of one year in full-time clinical work in a hospital.

approved by the Council and a further two years in the study of surgery or its allied sciences. The final examination consists of written and oral examinations in surgery and in surgical anatomy and surgical pathology, and a clinical examination. Alternatively, candidates may submit themselves for examination in obstetrics and gynaecology, or ophthalmology, or otorhino laryngology, the final examination to consist of a written, an oral, and a clinical examination in the special subject and in such medicine and surgery as is related to the special subject. The address of the Royal Faculty is 242, St Vincent Street Glasgow, C 2.

The Royal College of Physicians of Ireland (6, Kildare Street Dublin) grants Membership on the result of an examination taken in two parts: the first part being in general medicine and pathology, and the second in one of eight special subjects.

Two examinations—primary and final—are also required for the Fellowship of the Royal College of Surgeons in Ireland (St Stephen's Green, Dublin). The first is in anatomy, physiology, and pathology, and the second in surgery. A one year course for the primary starts in October each year and lasts three terms. There is also a postgraduate course in surgery arranged by the College with the co-operation of ten Dublin teaching hospitals.

The Society of Apothecaries of London conducts the examination of Master of Midwifery (M M S A), embracing anaesthetics, care, midwifery, and infant welfare and their relation to hygiene and preventive medicine. The examination, which is written, oral, and clinical, is held in May and November.

## THE COST OF MEDICAL EDUCATION

The fees charged at medical schools are not on any uniform basis. One estimate of the average cost of training, over six years, including books and instruments, is between £320 and £360, but tuition fees tend to rise, and so do examination fees in some instances. The figure named would cover the first M B in the case of degree students and the pre-medical examination in the case of students reading for the Conjoint.

Some detailed figures are given in the latest prospectus of the Leeds School of Medicine, which show an approximate total cost of the medical course for the M B, Ch B degree as £405 10s. This is made up as follows:

	£	s	d
Examination for matriculation and registration fee	4	0	0
Composition fee (paid by instalments)	265	0	0
Maternity hostel fee	35	15	0
Examination fees	18	0	0
Books, instruments, etc	75	15	0
Graduation and Convocation fee	7	0	0

The composition fees, which include Union fees, are payable at the beginning of each of the sessions from the first to the fifth in sums of £50, and at the beginning of the sixth, £15. This fee of £265 for the medical course if paid in one sum at the beginning is reduced by £10. All students are required to go into residence at the university maternity hostel for a period of approximately twelve weeks, and the fee is £35 15s for a single room. The approximate cost of instruments and books which the student must purchase during his course is considered to be as follows: 1st year, £18, 2nd year, £21, 3rd year, £14, 4th year, £5, 5th year, £2, 6th year, £2. On admission to the degree the graduate is required to pay a fee of £7 to entitle him to registration as a member of Convocation and to have his name inscribed on the parliamentary register on attaining the qualifying age.

There are of course innumerable awards—scholarships, bursaries, and the like—to assist and encourage the student. To take Edinburgh alone, some 50 entrance bursaries are tenable in the Faculty of Medicine, and there is a much larger list of fellowships, scholarships, and prizes for which students are eligible. In the Faculty of Medical Sciences, University College, London, there are six scholarships (value £200 each) awarded annually, known as the anatomy and physiology (B Sc degree) scholarships, tenable for one session immediately following the second M B.

The taking of higher qualifications involves further fees. The fee payable for admission to the primary examination for the Fellowship of the Royal College of Surgeons of England is

8 guineas, and to the final examination, 15 guineas. In addition, before the diploma is granted, Members of the College (those holding the L R C P, M R C S) pay 10 guineas and other candidates 30 guineas.

By the new rules of the Royal College of Surgeons of Edinburgh a candidate for the Fellowship pays an examination fee of 10 guineas for Part I and 20 guineas for Part II. After having passed in both parts of the examination he lodges a petition for his name to be placed for election as a Fellow and pays 25 guineas to the College funds. The fee paid by a candidate in the Membership examination of the Royal College of Physicians of Edinburgh is 35 guineas, when raised to the rank of Fellow he pays 38 guineas, exclusive of stamp duty. Under the new regulations shortly coming into force for the Fellowship *qua* physician and *qua* surgeon of the Royal Faculty of Physicians and Surgeons of Glasgow the fee for admission to the examination for Fellowship *qua* physician is 15 guineas, and the fee payable on admission to the Fellowship is 35 guineas. For the Fellowship *qua* surgeon the fee for admission to the primary examination is 8 guineas, to the final examination 15 guineas, and to the Fellowship 30 guineas.

Fees for special diplomas vary greatly. For the Diploma in Anaesthetics (R C P Lond, R C S Eng), the examination for which is now in two parts, the fee for admission to each part is 6 guineas, and 5 guineas is also payable before the diploma can be granted. In Edinburgh the fee for the primary examination for the D P H is 6 guineas, and for the final examination 10 guineas, for the D T M & H of the Incorporated Liverpool School of Tropical Medicine the fee for admission to the examination is 6 guineas and for the diploma 3 guineas. The class fees for the D P H in Edinburgh are 16 guineas for the primary course (one term) and 32 guineas for the final course (two terms). For the course in tropical medicine and hygiene at Liverpool the fee is 40 guineas.

## MILITARY SERVICE AND OTHER SERVICES OVERSEAS

### Training for Army Posts

Civilian doctors and released medical officers who have held a non-permanent commission in the R A M C during the emergency and were released before Oct 24, 1947, will be considered for appointment to short service Regular Army commissions in the R A M C for a period of eight years, the first four years of which will be on the Active List and the remainder on the Regular Army Reserve of officers. Civilian doctors will have direct appointment in the rank of lieutenant, and released medical officers, in certain conditions, in the rank of captain. Candidates must be not normally over 30 years of age, British subjects whose parents were British, and registered under the Medical Acts. During the last fifteen months of their service on the Active List they will be considered for appointment to a Regular Army commission, and if they do not want or are not selected for such commission they will receive, at the end of their four years short service on the Active List, a gratuity of £600. Conditions of service and forms of application can be obtained from the Assistant Director-General, Army Medical Services (A M D 1) 38, Hyde Park Gate, S W 7.

On the nomination of the Central Medical War Committee (B M A House, London) doctors are appointed to emergency commissions in the rank of lieutenant. During their service they can apply for a short service Regular Army commission and be subsequently considered for a permanent commission under the conditions stated above.

Officers commissioned in the R A M C may receive their post graduate service training at the Royal Army Medical College, Millbank, S W 1. Here a senior officers' course is held twice yearly. Formerly courses were also held for junior officers, but these are in abeyance for the time being. The senior officers' course is divided into three parts. The first consists of tropical medicine and entomology, military surgery, pathology, military hygiene, and psychiatry. The second consists of clinical instruction in medicine and surgery at London teaching hospitals and in specific fevers at the Brook Hospital, Woolwich. At the end of the first and second parts examinations are held, and there after officers are selected for training in the specialist subject for which they are best qualified or show aptitude. The third

part thus consists of specialist subjects to be undertaken by such officers as have qualified for further study in the preceding part of the course.

The instruction in tropical medicine at the College includes a course of lectures and clinical demonstrations, instruction in entomology is also given. The modern military surgery taught includes general and regional. Surgery of tropical diseases has its place in the syllabus, and stress is laid on the influence of tropical diseases on the management of surgical conditions in the soldier, both at home and abroad. The facilities offered by a small but very adequate department of anatomy, together with an excellent library of reference works and journals, are of great value to officers under instruction.

In the teaching of pathology the syllabus of lectures is designed to cover the subjects taught in the classes of tropical medicine, surgery, and hygiene. Specialists in pathology receive their first six months' training at the College except for the performance of necropsies. The syllabus includes separate courses of lectures and practical instruction in bacteriology in its widest sense, serology, haematology, biochemistry, histology and histopathology, protozoology, and helminthology. For selected officers a further six months' training in a chosen branch of their subject is arranged with various civil institutions. The pathology department also maintains the Army tumour registry, in which specimens of all tumours occurring in Army personnel, with reports as to their nature and histology, are maintained for future reference.

The hygiene department of the College in addition to the teaching of hygiene, has facilities for the carrying out of research of importance to the Army from the hygiene point of view. Well-equipped laboratories of adequate capacity exist for instruction in hygiene laboratory work of all kinds. There is also a well organized hygiene museum. The College is now recognized as a teaching institution for the CPH and the DPH awarded by the Conjoint Board and officers taking a specialist course in hygiene have the opportunity of taking the DPH and the DTM & H, for which most of the instruction is given at the College.

The course in psychiatry consists of lectures partly on clinical psychiatry and psychopathology and partly on the applications of psychological principles to morale, discipline, personnel selection, and other purely military matters. There are also demonstrations on clinical cases held at Banstead and Sutton Hospitals, and demonstrations of selection tests by a personnel selection officer. The school of radiology in the College affords ample material for teaching radiological diagnosis to officers taking the course.

There is no need of the reminder that military medicine is the pioneer in the preventive field. The most important movements in preventive medicine during the eighteenth century, alike in Great Britain and other countries, were initiated by military and naval surgeons.

### The Colonial Medical Service

The Colonial Medical Service offers an interesting career and provides exceptional opportunities for applying medical science in all its branches in territories which are undergoing rapid development. Medical officers are usually appointed in the first instance for general duties, which require all round ability and a balanced outlook on both preventive and curative medicine. There are also openings for doctors who hold the DPH or who have had previous experience in health work. In addition ample scope exists for research and field investigation, and officers who possess special interests and aptitude are encouraged to obtain such higher qualifications as will enhance their value to the Service. Appointments to the super-senior posts in the administrative and specialist grades are invariably made by promotion of officers in the Service who possess the necessary qualifications and experience. Full details regarding conditions and terms of service may be obtained on application to the Director of Recruitment (Colonial Service), Colonial Office Sanctuary Buildings, Great Smith Street, London, SW 1.

A limited number of research studentships were instituted in January, 1947, by the Secretary of State for the Colonies for graduates in medicine and cognate sciences who desire by this means to prepare themselves for research work in tropical medicine and related subjects. A graduate awarded a studentship is eligible for a maintenance allowance, assessed

according to personal circumstances. The maximum rates of allowance are £300 per annum at the Universities of Oxford, Cambridge, and London, and £260 per annum at other universities in the United Kingdom. The allowance is free of income tax. A studentship is normally awarded for a period of two years, subject to a satisfactory report at the end of the first year's work from the supervisor nominated by the Colonial Medical Research Committee.

Salaries, cost-of-living allowances etc., in the Colonial Service differ very considerably from colony to colony. The East African and Far Eastern salary scales are still in process of adjustment.

### Medical Missions

To medical men and women with a sense of vocation medical missionary service offers great opportunities. In China Christian missions have given the country a medical profession. In India and Pakistan they have helped to maintain high ethical and professional standards. In Africa they have pioneered rural health services and the training of subordinate staff. For undergraduates intending missionary service hostels are available in London and Edinburgh, also various scholarships. With regard to postgraduate studies at least eighteen months or two year appointments are advised for all and special diplomas or higher degrees for some. Some societies in addition require special missionary training. Offers for life service are expected but short terms are considered. Terms may be of from two to six years according to country or climate, with opportunities for postgraduate study during furloughs. Salary is on a missionary subsistence basis with allowances free passages and quarters and pension provision. There are schools for missionaries' children at home and in many of the fields.

Applications from students or qualified men and women should be made either to the secretary of one of the denominational or interdenominational missionary societies or through the local branch of the Student Christian Movement or the University Fellowship, or to the Chairman of the Medical Advisory Board of the Conference of British Missionary Societies, Edinburgh House 2, Eaton Gate, SW 1.

### ORGANIZATIONS TO JOIN

The newly qualified practitioner should immediately take steps after registration to join the British Medical Association and one of the defence organizations. Even if he is not in independent practice, but in a salaried position, perhaps in the service of a public authority, he will do well, by joining one or other defence society, to protect himself against the medico-legal hazards which even the most careful practitioner may encounter.

The Medical Protection Society (long known as the "London and Counties") (Victory House, Leicester Square, WC 2) has a membership of or approaching 25,000. During the past year it has gained over 1,500 new members. Membership is open to any registered medical or dental practitioner. This Society was the first to afford indemnity against adverse costs and damages, the first also to afford unlimited indemnity.

The Medical Defence Union (49, Bedford Square, WC 1) is the oldest medical defence organization in the country. It has over 32,000 members and has expended, since its inception, more than £323,795 in fighting and settling cases on behalf of its members. In 1947 the cases conducted by the Union numbered in all 1,586.

The Medical and Dental Defence Union of Scotland (113 St. Vincent Street, Glasgow, C 2) has a membership of some 6,000.

The annual subscription of all these societies is £1, with an entrance fee of 10s.

### The British Medical Association

The British Medical Association with which the Canadian Medical Association and the Medical Association of South Africa are affiliated, has a membership of about 58,000. In the United Kingdom three fourths of the members of the working profession are in the B.M.A. Members are elected by the Council of the Branch in the area in which they reside or if not resident in a Branch area (for example, serving with H.M. Forces), by the Central Council. The privileges of membership include participation in all activities of the Association.

ocal and central, in its government and the formulation of its policy, the receipt weekly of the *British Medical Journal* and its *Supplement*, the use of the houses of the Association (Tavistock Square, London, WC1, and 7, Drumsheugh Gardens, Edinburgh), and the help of the central staff in professional matters. The Association awards a number of prizes for research and the encouragement of important work. Six prizes, each of the value of £25, are awarded annually to medical students for essays submitted in open competition on a national basis, and £150 has been allocated for the award of regional essay prizes to medical students based on the four regions of the British Medical Students Association. The Association also has certain research scholarships which are awarded for a period of twelve months to accord with the academic year.

One of the latest developments in the Association is the establishment of an Empire Medical Advisory Bureau to assist members of the profession coming to this country from the Dominions and Colonies for postgraduate instruction and other purposes. The Bureau, now opened at BMA House, provides a personal advisory service to visiting practitioners, and one of its principal objects is to make available the fullest information regarding facilities for postgraduate study and, where necessary, to provide the required contacts and introductions.

The ordinary subscription to the BMA for members resident in Great Britain and Northern Ireland is 3 guineas but newly qualified practitioners are admitted to membership within two years of registration on a subscription of 1½ guineas, which continues until the end of the fourth year after registration, and the subscription is 2 guineas for members of not less than forty years' standing, for members of not less than ten years' standing who are retired from practice and for members not engaged in practice who are engaged whole-time in teaching or in research as distinct from routine laboratory work.

#### The Students' Association

The British Medical Students Association was founded in 1941 to promote the interests of medical students. It provides a method of communication between medical students of the various schools and regions and between British and foreign students. It publishes a journal, and has issued a catalogue of medical films. It has organized a number of clinical conferences in university centres, and its greatest and most successful effort in this direction was its organization of an International Medical Students Conference which took place, over a period of almost three weeks, successively in London and at Oxford and Birmingham, in July. The BMSA was ably represented on the Curriculum Committee of the British Medical Association which recently reported, and tributes were paid in the Council of the BMA to the value of the contribution made by its representatives. It holds an annual meeting in London usually extending over three days, and depends on local enthusiasm for its activities in the various schools. Recently it has created a new category of membership for qualified men and women, so that students who leave the student ranks on qualification need not necessarily feel themselves cut off from the student body. The offices of the Association are at BMA House, Tavistock Square, WC1.

### SPECIAL DIPLOMAS

#### Diploma in Public Health

The Diploma in Public Health (DPH) of the Conjoint Boards and the various universities is registrable with the General Medical Council. The preliminary and final examinations for the DPH under the English Conjoint Board are normally conducted twice yearly—in June and December—and candidates must give notice to the secretary of the Examining Board Examination Hall, Queen Square WC1, twenty-one days before the examination takes place and must furnish the necessary certificates. In Edinburgh University the final examination is held in July and October.

The preliminary examination includes written and oral examinations in the history of public health, the functions of central and local authorities, social security, international health organizations, nature and sources of information bearing on the health of the people, causal agents of infection and their sources of control, influence of environment on physical and

mental health, physical education, influence of heredity on health, and principles of health education. The final examination includes written examinations in physiology and biochemistry, food and nutrition as applied to public health, bacteriology, parasitology, and medical entomology as applied to epidemiology, mass aspects of disease, sanitation, etc., statistical data and methods, the law relating to public health, mental health services, occupational health, and a number of other subjects, also a clinical examination in infectious diseases and an oral examination in infectious diseases, epidemiology, and general and special hospital administration.

The London School of Hygiene and Tropical Medicine (Keppel Street, WC1) arranges courses for the DPH designed primarily for those who intend to enter the public health service in this country as medical officers of health. The course lasts one academic year of nine months. Examination for the certificate is held at the end of three months.

The Royal Institute of Public Health and Hygiene (28, Portland Place, W1) arranges courses of lectures and laboratory instruction by qualified teaching staff. Students completing the course are entitled to enter for examinations for the diploma of the universities and corporations.

#### Diploma in Tropical Medicine and Hygiene

The Diploma in Tropical Medicine and Hygiene of Liverpool University (DTM&H) has been combined in that form since 1946. Originally there were two separate diplomas. The diploma in tropical medicine was obtained at Liverpool by 978 candidates between 1904 and 1946, and since then the combined diploma has been obtained by 71. The examination is held in January or February and in April or May. The Incorporated Liverpool School of Tropical Medicine furnishes a course for the diploma twice yearly, each course lasting about five months. The examination consists of one paper on tropical medicine, one on pathology including bacteriology, one on parasitology, one on entomology, one on tropical hygiene, and one on sanitary engineering and tropical hygiene, and practical and oral examinations on the first four of these subjects.

#### Diploma in Industrial Health

For the Diploma in Industrial Health of the Royal College of Physicians of London and the Royal College of Surgeons of England (DIH, RCP Lond, RCSI Eng) candidates are admissible to Part I of the examination twenty-four months after having passed the qualifying examination in medicine. Both parts of the examination are taken in June and December unless otherwise ordered. Exemption from Part I may be obtained by those who hold a certificate in public health. The subjects in Part I are the same as in the preliminary examination for the DPH. The final examination consists of written papers and oral examinations on (1) the structure of industry, (2) international organizations concerned with public health and the law of industry, (3) industrial psychology, (4) surgery—rehabilitation and (5) medicine and surgery, dermatology, and ophthalmology applied to industry.

Candidates should note the possibility of additional expense for travel and maintenance, because attendance at factories and mines is required in the final course, and the places selected may be in various parts of the country. The same holds good for those taking the Diploma in Public Health, who are required as part of the final course to attend at the department of medical officer of health.

The Society of Apothecaries of London holds an examination in industrial health, embracing the history and legislation relating to the subject, occupational diseases, industrial environment, the practice of industrial medicine, and clinical medicine and surgery as applied to industry.

The Royal Institute of Public Health and Hygiene arranges courses for this diploma, and the practical instruction includes visits to industrial establishments, rehabilitation and retraining centres, and works' surgeries, and attendance at a skin and an ophthalmic clinic and at the accident department of a hospital.

#### Diplomas in Radiodiagnosis and Radiotherapy

Diplomas in this subject are granted by a number of bodies including the English Conjoint. For the Edinburgh diplomas (DMRD Ed and DMRT Ed) a written examination is held in June and September and the final in September and March.

## casting the burden of PERNICIOUS ANAEMIA

### EXAMEN LIVER EXTRACT IS

**painless** on injection

**proteolysed** preliminary enzyme digestion of the raw liver sets new standards of efficiency in extraction of the active principle

**potent** in the average case of pernicious anaemia in relapse, injections needed only once every 14 days and once every 3 or 4 weeks in maintenance

**protein-free** 'liver sensitization' is exceptionally rare

**standardized** optimum response thus assured

**inexpensive** average cost is four shillings per 1 cc

**fully active** in cases with subacute combined degeneration, though, when such neurological complications occur, more frequent injections may be needed

In clinical test a single injection of 1 cc of Examen is required to give over 14 days a response as shown in the chart above  
 $I = 0.93 - 0.214 E_0$  where  $I$  is the increase in red blood cells in one week, and  $E_0$  is the initial red cell count. The formula is derived from Della Vida B.L. and Dyke S.C. *Lancet* 1942 2 275

## "Blackcurrant Juice in Modern Therapy"

The latest information on the therapeutic uses of natural vitamin C has been brought together in practical form within the covers of a handy 8-page booklet. Here is an extract from the contents

In Infancy and Childhood  
 During Pregnancy and Lactation  
 In Dental Conditions  
 In Peptic Ulcer  
 In Fractures and Wounds  
 In Blood Dyscrasias and Haemorrhagic states  
 In Infections  
 In Skin Disorders  
 In Fatigue  
 In Other Conditions

A copy of the booklet will be gladly sent on application to Room 19A, H. W. Carter & Co., Ltd., Bristol 2, makers of Ribena Blackcurrant Syrup

## NEW TREATMENT FOR ASTHMA

Relatively free from the undesirable cardiovascular and other side-effects of adrenaline injections, 'Neo-Epinine', a recently-developed homologue of adrenaline, possesses marked advantages in the treatment of bronchial asthma. It may be given sublingually or by oral spray. The drug has been found to be an effective substitute for adrenaline. Superior to ephedrine, it does not cause sleeplessness.

### 'NEO-EPININE'

ISOPROPYL<sup>NOV</sup>ADRENALINE SULPHATE

Tablet brand compressed products for sublingual administration each containing 20 mgm. in bottles of 25 and 100. Spray Solution containing 1 per cent of drug in bottles of 10 c.c. Literature and samples on request.

BURROUGHS WELLCOME & CO (The Wellcome Foundation Ltd) LONDON

for B<sub>2</sub> vitamins  
**MARMITE**  
yeast extract

Among the nutrients known to be essential for the maintenance of health—mental as well as physical—are the vitamins of the B<sub>2</sub> group. Marmite contains riboflavin (1.5 mg per oz) and niacin (16.5 mg per oz) and also the less well-known B<sub>2</sub> factors such as pyridoxin, pantothenic acid, choline, biotin and folic acid, combined together in a palatable extract.

Present conditions are causing the medical profession to pay considerable attention to food in preventive and curative medicine. Marmite is therefore used increasingly in hospitals and, as vitamin supplements are specially indicated for mothers and children, it is ordered widely in welfare centres, schools and nurseries.

The course of study, full-time, extends over eighteen months for the Diploma in Radiodiagnosis and two years for the Diploma in Radiotherapy. During the first nine months the candidate attends lectures and receives a course of practical instruction. During the remainder of the time he takes part in the work of the department so as to extend his practical training.

### Diplomas in Psychiatry

The English Conjoint and several of the universities have Diplomas in Psychological Medicine. A course for the DPM is normally held at Maudsley Hospital (Denmark Hill, SE 5) in the early months of the year. The Conjoint Board in Ireland also has a DPM. The Diploma in Psychiatry of the University of Edinburgh (D Psych Ed) requires candidates entering for the examination to have spent a period of three years in a duly proportioned training in approved hospitals, clinics, laboratories, and other institutions—eighteen months' whole-time appointment in a mental hospital or psychiatric clinic, six months whole-time work in a neurological hospital or in the neurological department of a general hospital, six months' training in child psychiatry, including a three months' appointment on the staff of an institution for mental defectives, three months' training in psychology, and three months in the special study of psychiatry or neurology. Candidates can take these different periods in any order they prefer.

### Other Diplomas

The above are only examples of the special diplomas granted by the various bodies, and for full information the programmes and prospectuses of the bodies must be consulted. The University of Oxford grants a Diploma in Ophthalmology, the University of London a Diploma in Clinical Pathology, the University of Liverpool the degree of Master of Surgical Orthopaedics. The Conjoint Board in Ireland has Diplomas in Ophthalmic Medicine and Surgery and in Anaesthetics. A Diploma in Anaesthetics is also granted by the English Conjoint (DA RCP Lond, RCSI Eng). The examination for this is in two parts, the first part comprising physiology, pharmacology, and clinical pathology, with special reference to anaesthesia and analgesia and anatomy as it applies to these subjects, and the second part, anaesthesia and analgesia including pre-operative and post-operative treatment and clinical medicine and surgery in so far as it concerns anaesthesia. The English Conjoint also offers Diplomas in Laryngology and Otology, in Ophthalmic Medicine and Surgery, in Child Health, and in Physical Medicine.

## COURSES IN PSYCHIATRY

The National Association for Mental Health (39, Queen Anne Street W1) arranges training courses in certain aspects of psychiatry, mainly child psychiatry and mental deficiency. For the last seventeen years Fellowships have been given to enable qualified psychiatrists to obtain special training in child guidance at a recognized training clinic. Preliminary qualifications for the award of a Fellowship are the DPM, or equivalent experience in the psychoses, psychoneuroses and mental defect. Fellowships are tenable at a number of training clinics in England and Scotland. The usual course of training covers twelve months half-time. The course of training is recognized as a suitable qualification for the medical directorship of an education unit or a child guidance clinic.

The Tavistock Clinic (2, Perumont Street W1) has specialized as a centre for the out-patient treatment of children and adults suffering from psychiatric disability. The educational programme includes courses for psychologists and social workers as well as doctors. The twelve month half-time course for psychiatrists specializing in child psychiatry is organized jointly with the National Association for Mental Health. The number of students accepted for these courses is strictly limited.

The Institute of Psycho-Analysis (96, Gloucester Place W1) is a postgraduate course lasting about four years in psycho-analysis and technique. It includes a personal analysis and theoretical lectures and seminars and clinical work under supervision. The Institute does not set out to teach all aspects

of psychiatry, and general psychiatric experience must be obtained at other clinics and hospitals. Completion of the course to the satisfaction of the training committee qualifies for election as an associate member of the British Psycho-Analytic Society.

## ENTRANCE UPON PRACTICE

The majority of those who qualify will find their way into general practice, probably beginning as assistants. A much smaller number will be found in whoe-time posts in hospitals or in the public health service. A smaller number again will become consultants and specialists. The recent Spens Report traced the evolution of the specialist. After holding one or more house appointments he devotes himself to intensive academic study with a view to securing a higher qualification in medicine or surgery, and also with a view to obtaining, about four years after registration, a post which may be variously described as registrar or senior registrar, assistant or chief assistant, for which a higher qualification is normally required. In such a post he is given more and more responsibility, and on completion of his tenure he is ready for appointment to the staff of a hospital, when he will be recognized as having full specialist status. The Spens Committee, by the way, was impressed by the drastic selection to which aspiring specialists are subject, at every stage there is some elimination.

It is not necessary to recapitulate the conditions which the National Health Service imposes on a career in any of these branches of the profession. A summary of such conditions as affecting general practitioners, consultants and specialists, and public health medical officers was set out in the *Supplement* of June 19 (p 176), and an earlier statement on the remuneration of general practitioners was published in the *Journal* of June 5 (p 1096). The Report of the Spens Committee on the Remuneration of Consultants and Specialists, whose recommendations the Government has agreed to accept, was published in June and reproduced in the *Journal* of June 12 (p 1146).

With regard to public health medical officers, the remuneration and conditions of those in the service of local authorities are now under consideration in the light of the Spens Report. Pending the operation of permanent new scales, the recently revised "Askwith" memorandum will continue to have effect. The Council of the British Medical Association is urging upon the Government and local health authorities that the salaries of medical officers of health should be adjusted in the light of the Spens Report. Indeed, it is the intention of the Council that every type of medical remuneration shall be brought into line with the two Spens Reports (general practitioner and specialist), this will apply not only to the public health service but to the Colonial Medical Service and to the medical services in the Armed Forces of the Crown. During the past year the Council has made certain recommendations for the remuneration of whole time and part-time medical officers employed in industry. These were set out in the *Supplement* of June 19 (p 179).

### Remuneration of Medical Teachers

One point of some importance is mentioned by the secretary of the University of Aberdeen in reply to the usual inquiries about the work of the Medical School in the next session. He says that the report of the Spens Committee has caused some anxiety. There is no difficulty in the case of clinical professors, because the whoe-time salary for such posts is already well known, but great difficulties arise so far as whole-time lecturers in the various clinical departments are concerned. According to the Spens Report they should be receiving something like double what they are receiving at the present time. A still greater difficulty for the university occurs owing to the position of professors and lecturers in the medical scientific departments. It is pretty clear from the history of medical progress during the last fifty years that this has come mainly from the laboratory scientific department, and very little from the clinical side. The university therefore, regards it as a very serious matter that the holders of chairs and lectureships in medical scientific departments should be paid on a very much lower scale than those in the clinical departments, and is already taking steps to see what can be done to remedy the matter.

The Spens Committee expressed itself as doubtful whether it would be possible to secure the best men for teaching unless a higher total remuneration was offered

## THE PUBLIC HEALTH SERVICE

The public health service has been more widely affected by the changes resulting from the National Health Service Act than perhaps the rest of the profession realize. Hospitals have been transferred to the Regional Hospital Boards, and maternity and child welfare services from the relatively large number of we fare authorities, including non county boroughs and urban and rural districts, to the local health authorities under the Act—namely, about 150 county borough and county councils. Tuberculosis officers, hitherto employed by local authorities, are now mainly officers of the Regional Boards, though a method of joint appointment whereby they are still employed for part of their time by local health authorities for domiciliary and after-care work is being widely adopted.

Under the pyramidal structure which has always obtained in the public health service the number of chief posts has been relatively small in comparison with the total number of practitioners in the service. The effect of the Act has been to make the number of major posts still smaller, although a number of new types of post are being created. It is too early as yet to say what will be the ultimate shape of the service. Professor J. M. Mackintosh, in last year's Educational Number (Sept 6, 1947, p. 368), suggested that the loss of hospital services would be an ultimate benefit to the medical officer of health, as it would release him for his more proper duties in the promotion of health, with a return of direct interest in environmental services, especially housing. From the point of view of the medical graduate the public health service at the moment may not appear to offer a very promising career, but it is hoped that forthcoming negotiations on remuneration and conditions of service will result in prospects no worse than those for the general practitioner and the specialist.

The Ministry of Health estimate of the number of practitioners in public health in 1944 gave a total of about 2,000 in whole-time local authority appointments (excluding those in hospitals) in England and Wales. The number is not likely to have altered materially. About 200 whole-time tuberculosis officers have been transferred to the Regional Hospital Boards but other departments have increased their strength since the war.

### The New Entrant

The new entrant into public health work usually begins as assistant medical officer doing maternity and child welfare or school medical work or both. The future tendency will be for such medical officers to specialize more directly either on the obstetrical or child-health side and to have opportunities of keeping up clinical knowledge by interchange arrangements with hospitals or by clinical assistantships. For these appointments the DPH is not essential, and the Society of Medical Officers of Health has suggested that special experience in maternity or children's hospitals and the acquirement of some specialist diploma such as the DCH may in fact be more useful than the DPH itself. The Society, however, considers that a Certificate in Public Health, which can be acquired as the first part in the DPH curriculum, should be regarded as a basic qualification for anyone entering the public health service.

Above assistant medical officer level there are a number of senior posts defined in the Askwith Memorandum as "medical officers in charge of departments," which carry a higher rate of salary. These posts are, or should be, sufficiently well remunerated to make a career for those who do not aspire to the chief administrative posts as MOH or deputy MOH. For these two grades the DPH is a statutory necessity, and the course can be taken at two schools in London or at ten centres in the rest of Great Britain. Thus the public health service will still provide an interesting career for a man or woman interested in the preventive side of medicine, in the acquisition of knowledge of factors which affect the health of the people, and in the promotion of positive health.

For the above statement we are indebted to Mr G. L. C. Elliston, M.A., executive secretary of the Society of Medical Officers of Health.

## Correspondence

### Mental Health

SIR—One cannot help regretting that the recent International Congress on Mental Health, dominated as it was by the psychologists, could not have been more representative of the other social sciences, particularly education. Criticisms were made of teachers—criticisms which it should be said in all fairness could be made against members of other professions—and there was no one to point out that it is not the teaching profession but the educational system which must be revolutionized. There is, I think, little doubt that teachers will remain as they are so long as the educational system remains as it is.

Our upbringing and education, in the home and in the school, can largely obliterate or develop such psychic forces as guilt and aggression, which the Congress considered in relation to world peace. If parents had a greater knowledge of their own physical and psychological make-up it would improve their methods of training their children and if enlightened teaching along these lines were to be continued in the schools during the formative years one cannot help feeling that eventually there would be little need for specialists in psychology. So far as the schools alone are concerned training in human relationships should play a far larger part than it does to-day. Greater freedom of individual expression—an outlet for thought energy and word energy—is certainly as important, and far more important for later life, than the outlet for physical energy provided, for instance, by the traditional school games. It would be well to remember that the team spirit is of value only if it is not obliterated by the competitive spirit, with all its potentialities for developing and perpetuating aggression.

In short, there are many ways in which a drastically reformed educational system could contribute to mental health. In this endeavour the aid of psychologists would be invaluable. Until such a project is undertaken, however, there is little that individual teachers can do. Meanwhile one feels that the medical profession, which was prominently represented among the speakers at the Congress, would make a more positive contribution to human progress if it put its own house in order in the first instance. In the light of the general acceptance to day of the psychosomatic conception of medicine, the curricula and the whole method of training students in the medical schools are glaringly outmoded and inadequate. They continue to turn out doctors who have not only little knowledge of psychology but a positive antagonism towards it, and who feel that only one part of the individual is important and relevant—the body.

All illnesses, even if they are not technically psychosomatic, certainly include superimposed mental disturbances. If a person is ill he is totally ill, and there must be twofold treatment—for the condition and for the person with the condition. The danger of too narrow specialization—of failure to take the broad view—is always with us. With our present knowledge of the pervasive interaction of body and mind it is imperative that the G.P. should have a reasonable degree of psychological knowledge.

It would be well for members of the medical profession—in particular, the psychologists—to ask themselves where they are going. Do they want to supplant the teachers, politicians, statesmen, and sociologists? Would it not be better for them to concentrate on improving their own service to the individual and, through him, to the community? Meanwhile they should not try to give the lay public the impression that they alone have panaceas for all the world's problems. A profound knowledge of psychology is not restricted to those trained in it, as many classical and contemporary authors have shown. On the other hand, even the most highly trained psychologist might be nonplussed at confronting thirty or forty unruly, perhaps antagonistic, children in a hopelessly inadequate classroom. One cannot end without a word of praise for the excellent way in which the Congress was organized—I am, etc.

went to bed, but his wife was awakened by his stertorous breathing in the night and found that she could not rouse the patient. The doctor was again called and thinking that he had relapsed into coma, gave him a further 40 units ZPI. This time he did not come round and was sent into hospital.

On admission the patient was restless, with a peculiar to and fro conjugate roving of the eyes, each excursion taking about five seconds. The breath was free from acetone and the urine contained neither sugar nor ace one. The blood sugar estimated about 12 hours after the last injection of insulin was 28 mg % Glucose (6%) was given rapidly by intravenous drip, amounting to 2.8 litres, but the patient did not recover consciousness. Necropsy showed that the cause of the initial collapse was coronary occlusion.

It is possible that the diagnostic blunder made here weighed the balances against the patient recovering from his heart attack by so depleting the blood of sugar for a number of hours that irreversible changes were produced in the central nervous system—I am, etc,

Edinburgh

D STEWART McLAREN

### "Mushroom" Poisoning due to *Amanita Phalloides*

SIR—The following quotation is from Dr Paul White's book (1945) on diseases of the heart "The mushroom *Amanita phalloides* has been reported to have been the probable cause of temporary right bundle branch block (Hyman 1928)." Dr David Lewes (Aug 21 p 383) also refers to Hyman's report in his article on poisoning due to this fungus.

I do not think that Hyman's patients were suffering from poisoning by *Amanita phalloides*. The course of their illness as he described it was as follows. Three hours after ingestion the four people fell ill with violent abdominal pains, nausea, and vomiting, and two of them had diarrhoea. In one there was an agonizing frontal headache, vertigo and blinding flashes of green light. After eight hours the abdominal signs in this case had completely disappeared, but he then became stuporose and could be roused only with difficulty. Ten hours after taking the fungus the cardiac irregularity was noticed. Hyman says that a specimen of the mushroom gave the typical silver-spoon reaction. After intravenous administration of glucose for thirty hours the patients were fit for transfer and after a few days they were quite well.

The short incubation period, the benign course, the rapid return to normal health (and, I suspect, the "typical silver-spoon reaction"), all speak against *Amanita phalloides* as having been responsible for the symptoms and the heart block. Indeed, there is nothing to suggest that this fungus had been taken. It is a pity that Hyman's statement is beginning to be taken seriously and apparently without any critical appreciation of the clear report he gives of the clinical condition of his patients.

This is the way that myths arise, and I trust that this one will be scotched before it is copied by even more authors. The only mistake made by Hyman was in identifying as *Amanita phalloides* the fungus which made his patients ill. It would be interesting if Dr J Ramsbottom would give his opinion on this matter—I am, etc,

### Gangrene after Scorpion Sting

SIR—In his report of a case of gangrene after scorpion sting Dr M. Y. Ansari (Aug 21, p. 388) infers that it is a very rare condition. Actually it is not uncommon. A scorpion often stings the same victim several times. I have several times seen a young adult with three or four circular marks on the back due to putting on a shirt with a scorpion concealed in the inner folds of the garment. The circular marks are often 7–8 cm in diameter, the first a black disk of dead skin and subcutaneous inflammation, the second a much inflamed plaque with a central necrotic area about 5 mm in diameter, the third a reddened and swollen circular disk of skin, with no necrosis, the fourth may be just an erythematous area with a circular margin a good deal smaller than any of the earlier lesions. Before the second world war we used anti-scorpion serum made by a German firm, but I think such a serum is now manu-

factured in this country. The remedy must be used soon after the patient has been stung. Dr A. H. Mohammed (*Lancet* 1942, 2, 364) describes the preparation of anti-scorpion serum. He advises the simultaneous administration of atropine and ergotoxine. Young children can be killed by a scorpion sting, for them the anti-scorpion serum is essential—I am, etc,

FRANK MARSH

### Repair of Indirect Inguinal Hernia

SIR—It is refreshing to read a letter like that of Mr Frank Forty (July 31, p. 268) which gets away from anatomical and physiological theories and faces the fact that in the hands of experienced surgeons the bulk of "recurrences" are not recurrences at all but new and direct herniae at the inner end of the inguinal canal.

Mr Forty meets this challenge in one way, I in another, but at least we both appreciate two essential points: (1) the importance of exposing the pubic spine and the passage of the crucial first stitch through the dense fibrous structures attached to it, and (2) the importance of relaxing the conjoined tendon so that it is not sutured to the inguinal ligament under tension. If these points are attended to it will be found that the actual percentage of "recurrent" herniae is diminished to a very low figure. Similar results should be recorded by those who claim that a new hypothesis is of fundamental significance—I am, etc

### Use and Abuse of Tonsillectomy

SIR—I endorse Mr T. B. Layton's statement (Aug 7, p. 310) that the profession as a whole should reconsider its approach to tonsillectomy. But it would be disastrous to leave the decision to the parents. Anybody with experience in school tonsil clinics knows that parents who bring their children very often say,

"I want my child's tonsils removed," and are more than displeased when told that tonsillectomy is not advised. The point however I should like to emphasize is that far too many tonsils are being removed where all that is required is simple adenoidectomy. This is where a clear differential diagnosis must and can be made. Although complete removal of adenoids with out damage to the eustachian tube and the pharyngeal mucosa is a much more difficult and skilful operation to perform, it is of course a smaller surgical intervention from the patient's point of view and less liable to complications. Unless there is definite pus in the tonsils and there is tonsillar adenitis present all the benefit from the operation called "Ts and Ads" is derived from the removal of adenoids. I see on an average 800 to 900 patients a year in my capacity of aurist to the Ealing Borough Council, and over a number of years I have practised adenoidectomy only where the tonsils were not obviously infected, with very rare exceptions I have not been obliged to do a subsequent tonsillectomy. I appeal for careful and complete adenoidectomy without removal of tonsils in every case—I am, etc,

ARTHUR MILLER

### Prevention of Venereal Diseases

SIR—I have read with great interest the replies to Lord Horder's letter (July 17, p. 171) on the prevention of venereal disease. One fact seems to stand out clearly, and it is this—that the crux of the whole matter is the efficacy of prophylactic measures and the extent of their efficacy. This is clearly admitted in the letter of Dr E. W. Assinder (July 31, p. 269). If it can be shown that such measures are in a large degree effective there can be no doubt that it is the plain duty of the State and medical profession to disseminate the knowledge of these and provide facilities for their adoption.

I ask myself and I should like to ask the writers of some of their letters, this question: If prophylaxis could be shown to be 100% effective would they still be against it? I cannot help thinking that the moral side would outweigh the social and humanitarian aspects. I would agree with Dr G. L. Russell (p. 268) that VD is not only a medical and social problem but also a human one, but I do not think it is to any great extent a moral one. It is because it is a human problem that all the teaching of the churches has failed to bring about St Paul's ideal that a man should be "the husband of one wife blameless"—*Natuiam expellas furca tamen usque recurrit*.

Illicit sexual intercourse is probably as widespread to day as it ever was. The incidence of V D among our troops in Germany was 185 per thousand. We must suppose that unless every case or most cases of illicit intercourse resulted in infection the incidence of promiscuous sexual relations must have been much higher than this. We must therefore conclude that a very large proportion of Service men are promiscuous, and I doubt if all the exhortations of COs and padres will much reduce this. How far is this a moral question? Morality must always be a relative matter, conditioned by the religious, social, and economic structure of a people. There is no absolute morality, no code laid down by an external law-giver. Probably the only absolutely moral people were, before the missionaries got there, some of the races of the Pacific Islands where sexual intercourse was looked on as an absolutely natural function, and where there was no law in this respect, except some taboos, and therefore no sin.

It would be of great interest to know whether, if Dr R C Webster (p 269) has found rubber and chemicals inadequate to protect the hands from infective discharges, he has discovered other means, or if he has had to abstain from such contacts—a difficult matter for a syphilologist. I am by no means advocating indiscriminate sexual relations in our society as now constituted, but I do maintain that the question of V D will only be obscured if tackled from its doubtful moral rather than its sound economic social and human side—I am etc.,

Taynuilt Argyll

P F CHAPMAN  
Col. I.M.S. (Ret.)

SIR—The problems of venereal disease and its prevention are of paramount concern to military authorities, and, while it is not claimed that the solution applied in Egypt during the recent war is applicable to all countries, yet as it was so successful then it is worthy of mention.

In the early part of 1942 venereal disease was a serious cause of hospitalization of troops, producing more admissions than battle casualties. 52% of the V D cases contracted their disease in the controlled brothels of Cairo. After an investigation into this problem in March, 1942, I suggested that all the brothels in Cairo be put out of bounds, that various counter-attractions such as swimming-pools, cinemas, and sporting events be supplied, and that prophylactic ablation centres (PAC) be decentralized and taken out of the control of the military police.

This proposal met with vigorous opposition from many quarters, including medical, owing to the widespread opinion, as held by Dr W B Laing (Aug 21, p 400), that "legalized and controlled prostitution as was carried out until recently in France is the only sure method of V D control." My argument was that this control gives false security and encourages men to take risks. Thanks to the support of Brigadiers A Chrystal, the Area Commander, A E Richmond, then DDH, and R Lees, the adviser in venereal diseases, the opposition was overcome and the brothels were put out of bounds in October, 1942.

As I remained in Egypt until June, 1945, I was able to observe the results of this measure. To summarize, it was found among the British troops that (1) The number of exposures to infection as judged by the attendances at PACs fell to one-tenth of the pre-closure figures. (2) The incidence of V D expressed as a ratio per 100,000 ration-strength (including leave personnel) dropped to one-quarter of the former figure. (3) Cairo was held responsible for only 17% of M.E.F. venereal disease instead of over half. (4) The general conduct, morals, and morale of the troops in this area so improved that on the eve of his departure from Egypt Brigadier Chrystal stated that the closure of the brothels was well worth while for this improvement alone, even if the V D rate had remained unaltered, which of course it had not.

Dr Laing suggested in his recent letter that the termination of legalized and controlled prostitution in France has led to an increase in V D. This is a most controversial statement, for there are several other factors which may account for the increased incidence—I am etc.,

Beechley Bluffs

A MICHAEL CRITCHLEY  
Late A.D.H. Cairo Area M.E.F.

SIR—As a medical student and also as a Christian I am disturbed by the letter of Dr W B Laing (Aug. 21, p 400) on the subject of the prevention of venereal disease. I would say that the practical solution of the problem of the spread and

control of such diseases is more difficult and involves wider considerations than almost any other group of infectious diseases. Having made this general statement I would like to refute the ideas of Dr Laing that the Church is responsible with the State for "driving sex into back streets and sordid lodgings," an outlook which "favours the spread of V D" and helps to "transform sexual experience from something beautiful into something ugly and shameful." Such crooked thinking is dangerous, but in one who presumably has an influence in the local community it is a shocking revelation—I am etc.,

Manchester 20

P WHITE

SIR—It is regrettable that the ancient error as to the value of controlled prostitution should be again brought forward by Dr W B Laing (Aug 21, p 400). Since even a venerologist cannot exclude syphilis and/or gonorrhoea in a woman without several months' observations and tests, the futility of cursory examinations is obvious. Controlled brothels were out of bounds in several cities during the recent war: this was not on moral grounds, but as a protection against infection. It is a curious fact that in written controversy on the prophylaxis of venereal disease, as also in verbal discussion, the non-specialists are optimistic, the venerologists incredulous.

I have carefully avoided entering on the moral and social aspects of this problem, and would suggest to Dr Laing that the views of a doctor in his professional capacity as to the value of marriage certificates and chastity as an ideal have no special value. It is not easy to see how the bringing of promiscuous sex relations "out of back streets" by a change in the official outlook of Church and State "would lower the incidence of disease and automatically make the adventures of our patients "beautiful." *T. pallidum* and the gonococcus are no snobs and flourish at any address. In my experience among races whose moral outlook is not that of European Churches and States venereal diseases were very prevalent, and the beauty of these peoples' lives was not particularly obvious, while neuroses seemed quite common.

But let the cobbler stick to his last as a venerologist. I repeat there is no method of prophylaxis of venereal infection which in ordinary life affords any significant degree of security, and in that categorical statement is included condoms and/or chemicals, regulation of prostitution, arsenicals by mouth, measures applied under supervision, and those left to the individual—I am, etc.,

### The BMA Under Fire

SIR—To defend the BMA by saying (Aug 21, p 392) that no organization is perfect but, so long as it acts in good faith and with courage, it can withstand criticism recalls Mr Churchill's remark about our pre-war Government—that it is a fine thing for a Prime Minister to be honest but an important thing for a Prime Minister to be right. Was the BMA right in refusing to allow any discussion of terms of service during the past six years? It has been obvious for all of that time that sooner or later the BMA would offer the services of the profession to the country. When any of us is going to sell something important his first step is to get an opinion of what it is worth: satisfactory negotiation is impossible otherwise. The BMA had a real duty to find out what value the profession put on its services. The evidence given to the Spens Committee would pretty certainly have been affected by such information. It is a doubtful argument to say that a majority of practitioners have approved the Spens Report. A majority of practitioners opposed the health service in the second plebiscite, but the minority view was adopted then. Anyway, if the BMA had put discussion of terms on divisional agendas years ago it would have been in a far better position to appreciate the difficulties of what it regards as a minority now, instead of spending six years on principles, of which it evolved seven, or slightly more than one principle per annum. I challenge any reader to write down at once those principles (if he remembers them), to reflect on how many have proved essential, and to say that they justify six years of planning committees and executive, divisional, representative, and council meetings. So far as the health service goes no other result emerged.

We still have no agreed opinion as to how many patients a doctor can look after properly, or what income he should have

There is no conception of what proportion of that income used to come from no-longer existent contracts or appointments to hospitals, public authorities, schools, etc., nor what is still needed to perform that work in the nature of qualified assistants, domestic or dispensing staff, or housing accommodation. All these points might have been discussed, would have attracted larger attendances in divisions, given a feeling of reality to the matter, and accumulated essential information qualifying the B.M.A. to advise in drafting the regulations which are the important things in the Act now. There was not even a statement that no medical practitioner ought to suffer appreciable loss by entering the service yet, if the service has seemed to start smoothly, that is because quite a lot of the profession are resigned to more work, often for less pay. The essential trouble with the B.M.A. is that it is impractical. I hope more correspondents will write frankly about their difficulties, and that the B.M.A. Executive will recognize these more readily than (to judge by letters I have received from wide spread correspondents) they have hitherto. I am a strong believer in the possibility of a successful service, but we must be much more honest with ourselves and the public than B.M.A. policy has hitherto allowed us to be—I am, etc.,

Hove Sussex

### Service Doctors in Far East

SIR,—In his reply (Aug 7, p 311) to my letter concerning the service of doctors in the Far East I feel that Major-General R Edgeworth-Johnstone has either deliberately or unintentionally side-tracked the issue. In addition he appears to be ignorant of the regulations governing the granting of family passages. Contrary to what he states, the grant of an Army passage is *not* dependent on the availability of Army quarters. If the officer concerned can provide private accommodation for his family, a passage may be granted. There are in fact two scales of allowances, one for the officer occupying Army quarters and one for the officer in private accommodation.

The points system which the Major-General so carefully outlines has little bearing on the allocation of family passages. I personally know three officers who have the same or less number of points than myself and whose wives were granted passages to Singapore and live in private accommodation. These concessions appear to be available for some and not for others, and it seems to be the policy to put all possible obstacles in the path of the conscript doctor who wishes to bring his wife out to join him.

Many doctors, despairing of the administrative battle, have brought their wives out at their own expense. These officers have been in receipt of the increased allowance paid to officers living with their wives out here. The officer under the age of 25, in addition to receiving only the half-scale ordinary marriage allowance, is on no account entitled to a family passage for his wife. Nor if he arranges and pays for the passage himself is he entitled to the increased local marriage allowance without which it is impossible to live.

I think that penalization of the married officer under 25 is grossly unfair at any time. When it amounts to enforced separation at a time when separation is not necessary (v the large number of military families at present in Singapore) it is nothing short of criminal. No amount of official explanation will make it anything else—I am, etc.,

### Shortage of Nurses

SIR—One of the most important factors preventing the building up in this country of a successful comprehensive health service is the shortage of nurses. Hospitals and other branches of the Health Service are carrying on, in some cases struggling on, with nursing staffs much below the minimum requirements. Hospital beds are lying idle while waiting-lists are expanding. The over-burdened nurses are becoming more dissatisfied and a vicious circle has been set up reducing further the already too few.

Much has been done to try and improve the nursing shortage. First, the Rushcliffe Committee introduced better salaries and conditions of service. Their original recommendations, followed by many successive improvements were thought to be sufficient inducement, but these have obviously failed.

Then the Working Party on the Recruitment and Training of Nurses, under the chairmanship of Sir Robert Wood, investigated very thoroughly the whole matter, and published a very comprehensive report of 116 pages, which in my opinion points out very definitely the seriousness of the position but suggests little or nothing to improve the situation within the next twenty-five years.

It must be admitted that all efforts up to now to build up an adequate nursing service have failed. The reasons for the shortage must be investigated further, and other attractions used to counteract them. The aims to be achieved are (1) to attract sufficient numbers into the profession, and (2) to attract the correct types of persons into the profession (I say persons to include both sexes).

The answer to (1) would appear simple. Give them a big enough salary and you will get the numbers. But what would be the result? Large numbers would commence training with no intention of completing it, others, intending to complete their training and make a profession of nursing, would be so disgusted with some of their colleagues that they would resign, and there would be no incentive for a junior nurse to reach senior status and carry more responsibility. We must, therefore, have such conditions as will achieve both aims—sufficient numbers and correct types.

In my opinion the only way to do this is first to raise nursing to the status of a profession, in fact as well as in name. A student nurse should be considered and should consider herself of equal status as a student of medicine or law or accountancy or any other profession. How is this to be achieved?

The solution, I think, might be found along the following lines: (1) Do not keep increasing the salary of a student nurse, but as soon as she qualifies give recognition to her professional status, and give her an adequate salary—e.g., £300–£350 per annum. This, of course, should increase as her professional skill and responsibility increases. (2) For persons who could not afford the three to four years of training with low salaries, scholarships should be granted to those who prove themselves suitable. Scholarships could be considered by examination or interview. (3) Living and working conditions must be improved in many hospitals. To do this building priority must be given for nurses' homes and hospitals.

I feel sure that only by working along these lines will the strength and status of the nursing profession be improved. And it must be done now. Already the nurses themselves, and many of them are very excellent nurses of the best type, are beginning to lose sight of the fact that nursing is a glorious and noble profession. Backsliding is easy, but progress can only be achieved by strong and immediate efforts—I am, etc.,

South Shields

### POINTS FROM LETTERS

#### Guild of St Luke

Dr H M RAVEN (Broadstairs) writes: There have been several communications in the *Journal* lately on the subject of doctors, clergy, and healing. The main link between the two professions used to be the Guild of St Luke. The officers of the guild are apparently not functioning, I believe the Provost, Dr Bokenham, has died. Would it be possible to revive the guild, which has had an honourable past and which must still contain many members, including myself. Perhaps a meeting of old members and others interested, to be held at B.M.A. House, would be allowable and useful. This letter may catch the eye of an ex-official of the Guild of St Luke and I hope he may feel inclined to take the initiative.

#### World Food Shortage

Dr H M STEPHENSON (London SW 5) writes: In a leading article (Aug 14, p 345) you praise the optimism of Sir John Boyd Orr for his belief that the nations of the world may yet show as much concern about feeding the 2,500 million people in the world as in feeding the 2½ million people in Berlin. A facile optimism can be shown by anybody who belittles a problem by misstating it. The problem is not to feed 2,500 million people but to feed 2,500 million people who are increasing at the rate of 1% per annum. The 40 million square miles of cultivable land in the world might support in food a total of 6,000 million people. At the present rate of increase that total will be reached in about 50 years. Improved agriculture may defer the disaster for perhaps another decade. I can think of no remedy that mankind—which includes their churches—would accept. But surely realizing the truth of a problem may induce first a few and then the many to try to solve it.

## Obituary

J E H ROBERTS, OBE, MB, FRCS

James Ernest Helme Roberts died on Aug 25 at his home in Ottershaw, at the age of 67, after a long illness during which he maintained a remarkably keen interest in the activities of all his old friends, although he was fully aware of the fatal prognosis. He will go down in medical history as one of the great pioneers in surgery of the chest, for his interest in this specialty started in the 1914-18 war and was sustained through all the vicissitudes of its infancy, those practising thoracic surgery to day must realize how much they owe to the courage of men like Roberts.

Born in West Bromwich, Staffs, he was educated at King Edward's School, Birmingham, and subsequently studied medicine at St Bartholomew's Hospital. After qualifying MRCS, LRCP in 1906 he graduated MB, BS with honours in surgery in 1908 and proceeded to the Fellowship of the Royal College of Surgeons the following year. Of numerous house appointments there is no doubt that Roberts valued his period of service as house-surgeon to Mr C B Lockwood at St Bartholomew's Hospital more than any other, for he repeatedly referred to his teachings. Roberts's amazing powers of observation were probably developed through his study of natural history, but Lockwood's example may well have emphasized for him the importance of training his faculty. He was later appointed part-time demonstrator of pathology, and this influenced his approach to medicine throughout his career, for his hospital visits were rarely completed without his "dropping in" to see the pathologist to discuss some problem connected with the work in the ward. Concurrently he held the post of chief assistant to the orthopaedic department, and this period of training was never forgotten, for even when his surgical work had become almost confined to the chest his interest would always be particularly aroused by any abnormality of the bones or joints. A child with an obstructed diaphragmatic hernia became a doubly fascinating problem when discovered to suffer from diaphragmatic aetiology as well.

Roberts learnt to appreciate the importance of studying children and their diseases as a house-physician at Great Ormond Street, and in 1913 he was appointed assistant surgeon to the East London Hospital for Children. Children are better judges of human character than many would suppose, for they choose for their adult friends those with patience, kindness, and absolute honesty, all of which Roberts had in abundance. These basic qualities, combined with his special training, were responsible for his remarkable success in handling children. He served in the first world war from 1914 to 1919 and was thrice mentioned in dispatches. The excellence of his work as a surgical specialist with No 5 General Hospital and No 41 Casualty Clearing Station was recognized officially by the award of the OBE. Before 1914 the surgery of the chest was more or less confined to drainage of empyemas, and it was during his war service that Roberts, having dealt successfully with large numbers of major wounds of the chest, realized that the knowledge gained might well be employed in bringing relief to conditions other than wounds. After the war his work for the wounded was continued by his appointment as surgeon to Queen Mary's Hospital, Roehampton.

In 1919 he was appointed assistant surgeon to St Bartholomew's Hospital where he was destined to become senior surgeon before his retirement from hospital practice in 1946. Practitioners of to-day who had the good fortune to serve Roberts as dressers in their student days will recall how much they owe to his teaching. He always stressed principles rather than details and always emphasized the practical nature of the work of a doctor. He prided himself on his knowledge of practical nursing and there must be many who remember the embarrassment of being asked to describe exactly how to prepare raisin tea or Imperial drink. Nothing annoyed Roberts more than cloaking ignorance with verbosity and his irritation would reach its zenith if this was wofully done for decent as an anaesthesia to him. He was a purist and insisted that others

should be equally accurate. The expressions "almost," "nearly," "not quite" would always bring forth one of his fund of stories. His teaching in general surgery was remarkable for its clarity and simple logic, any student who heard him discuss intestinal obstruction would never afterwards delay in taking steps to confirm such a diagnosis. Although his name will always be connected with chest surgery, he was ever in the vanguard of general surgical progress. For example, he was performing gastrectomies for intractable gastric ulceration when many other surgeons were still practising gastro-jejunostomy. There was no limit to his courage as a surgeon so long as the patient's disease warranted drastic measures, and in the operating theatre he was at his best when undertaking truly formidable procedures.

It was his appointment as surgeon to the Brompton Hospital in 1919 which gave Roberts the opportunity to develop his interest in chest surgery and so to become one of the world's most famous thoracic surgeons. He was not a prolific contributor to medical literature, so that the propagation of his work was largely by personal teaching, which always proved a great stimulus to the younger surgeons because he was ever ready to discuss their problems. He is justly credited with being the originator of an excellent plastic operation for some cases of chronic empyema which is now usually designated the "Roberts flap operation". He was a frequent and much-valued speaker at meetings, and was at one time president of the Medical Society of London, of the Society of Thoracic Surgeons, and of the Tuberculosis Association. His desire to do everything possible to raise the standard of treatment of the tuberculous, and his ability to divest a problem of its trappings so as to see the essentials, resulted in his serving on the Joint Tuberculosis Council for more than ten years and on the Standing Advisory Committee on Tuberculosis to the Ministry of Health for four years. He was particularly interested in the international aspects of surgery, and was for many years the British delegate on the committee of the Societe Internationale de Chirurgie. His work was recognized abroad by his election to honorary membership of the American Association of Thoracic Surgeons and of the Polish Society of Surgeons.

Roberts generated a striking loyalty and affection among those who served him, and there are many who feel a deep personal loss in his death. Fundamentally a shy man, he covered any self-consciousness with a forthright, almost aggressive manner which was not always completely understood by his contemporaries. His interests were by no means confined to medicine, so that there was hardly any subject of conversation to which he could not make some valuable contribution. He was an enthusiastic alpine gardener, and was probably more proud of his awards as a member of the Alpine Garden Society than of many surgical triumphs, he was also a well-known authority on dragon-flies. His leisure pursuits were such that he was well equipped to enjoy the retirement which has been denied him. To his widow, a sister of the late R C Elmslie, the orthopaedic surgeon, the sympathy of all his colleagues and friends will be extended.

P R LOWE, OBE, MB

Dr P R Lowe, who died on Aug 18 at the age of 78, had an international reputation as a student of ornithology and was for many years in charge of the bird-room at the British Museum.

Percy Roycroft Lowe was born at Stamford, Lincolnshire and was educated privately and at Jesus College, Cambridge, and Guy's Hospital. He graduated in 1899, and soon afterwards became senior house-physician at Leicester Infirmary, and later senior house-surgeon at the Derbyshire Royal Infirmary. He was one of the civil surgeons selected by the War Office for service in the South African war and was appointed medical officer in charge of Princess Christian's hospital train. It was during his service in the field that his interest in ornithology began. Returning from South Africa, he became private physician to Sir Frederic Johnstone, Bt, and with him made a number of voyages to the West Indies and collected no fewer than 3,000 birds from practically every island in the Caribbean Sea as well as from Cape Verde, the Canaries, Madeira, and the Azores. In 1916 Dr Lowe served in the Mediterranean in Lord Dunraven's yacht, which was

fitted up as an officers ambulance ship and plied from Malta. Returning home, he was commissioned as a captain in the R A M C and was appointed to command Princess Christian's new ambulance train, a post which he filled for three years.

At the end of the war Dr Lowe succeeded the late Mr W R Ogilvie Grant in charge of the bird-room at the Natural History Museum and set himself to reorganize the collections there. He was given charge of the osteological collection, which previously had been kept entirely separate from the collection of skins. Over the next twenty years Dr Lowe contributed greatly to the classification of waders and to the understanding of the relationship of these birds to one another as well as to other families and groups. His paper on the finches of Gough Island shows the thoroughness with which he investigated every problem, and he was a so responsible for important work on the anatomy of ostriches and penguins. The British Section of the International Committee for Bird Preservation, of which he was first secretary and then chairman for many years owed much of its effectiveness to his untiring energy. Dr Lowe was vice-president of the British Ornithologists Union from 1934-6 and president from 1938-43. As recently as 1946 he was awarded the Salvin Godman Gold Medal of the Union for outstanding work on bird anatomy and on the protection of birds.

Dr ANDREW RADBURNE FULLER, of Perranporth, Cornwall, died suddenly on July 19 at the age of 55. He was born in London, the elder son of Dr Andrew Fuller, chief medical officer for England and Wales under the Local Government Board. He was educated at Leighton Park School and St Mary's Hospital, at both of which he won open scholarships. In September, 1914, he went to France with the Red Cross as a medical orderly, returning in 1915 to work for his final examination, which he took in 1916. He was immediately commissioned in the R A M C and posted as a battalion M O to a division in the Battle of the Somme. Early in 1917 he was invalided home to spend many weary months in hospital, before being invalided out in 1920. Dr Fuller subsequently took his DPH and joined his father, who was then in practice at Perranporth. There he remained until his untimely death. He was always a keen athlete and was a first-class cricketer and tennis player, holding the Cornish singles championship for three successive years and also playing first couple for the county. Dr Fuller will long be remembered by all in Perranporth and the surrounding district for his exceptional medical ability and devotion to his work, which he combined with a sincere and unselfish love of his fellow-men. He upheld the finest traditions of the profession. He married in 1925 Elizabeth Mary, younger daughter of Dr Peter Ingram, of London, who, with two children, survives him—C B S F.

Dr ROBERT EVANS THOMAS, whose sudden death on July 30 at the age of 66, came as a shock to his friends, was associated for some twenty-seven years with the Bath Health Department, for much of that time as deputy medical officer of health and deputy school medical officer. He was the son of a Bristol solicitor and went to school at Clifton and Felsted. Receiving his medical education at Bristol, he qualified in 1906, graduated MB, BS two years later, and proceeded MD in 1911, taking the DPH in 1915. Resident posts experience of private practice, and service in France during the 1914-18 war were followed by an appointment in the school medical service at Manchester. A little later, in 1920 he came to Bath, and he remained there for the rest of his life. Dr Thomas's most notable work was done in connexion with maternity and child welfare and school medicine, and both those services in Bath owe a great deal to his keen interest, sound judgment, and outstanding clinical ability. A crippling arthritis, which he bore with admirable courage, led to his retirement from his post as deputy medical officer in 1938. A year later, however, on the outbreak of war, he was recalled to take charge of the municipal antenatal clinics at Rivers Street, where his services were so much appreciated that he continued to attend several times a week until the day of his death. His patients soon discovered the deep personal interest Dr Thomas took in their welfare, and they had the greatest confidence in whatever advice he gave. He gained the sincere respect of all with whom he came in contact and will always be remembered by his colleagues with the most friendly and affectionate regard—J F B.

## Universities and Colleges

### UNIVERSITY OF WESTERN AUSTRALIA

On the occasion of the Australasian Medical Congress, held at Perth last month, the honorary degree of DSc was conferred on the following: Frank Macfarlane Burnet, MD, FRCS, Professor of Experimental Medicine in the University of Melbourne and Director of the Walter and Eliza Hall Institute for Medical Research, Melbourne; Sir Henry Simpson Newland, CBE, DSO, MS, FRCS, FACS, FRACS, a Vice-President of the British Medical Association, President of the Federal Council of the BMA in Australia for the last 18 years, and President of the Royal Australian College of Surgeons from 1929 to 1934; James Calvert Spence, MC, MD, FRCP, Professor of Child Health in the University of Durham; and Frank Burton Walsh, MD, Professor of Ophthalmology at the Johns Hopkins Medical School, Baltimore, USA.

### SOCIETY OF APOTHECARIES OF LONDON

A course of ten postgraduate subscription lectures on modern therapeutics will be delivered in the Hall of the Society (Black Friars Lane, Queen Victoria Street, EC) between Oct 18 and Nov 5, at 5 pm both dates inclusive. The fee for the whole course is £3 3s (single lectures, 7s 6d). Details of the lectures will be published in the diary column of the *Journal* week by week.

At a recent meeting of the Court of Assistants Professor E C Dodds, FRCS, was re-elected Master of the Society for a further year from Aug 17 and Mr Duncan C L Fitzwilliams and Dr Frank D Howitt were elected Wardens. The reports of the deaths of Dr C H T Ilott, late Assistant, and Sir George Newman, Honorary Freeman, were received with great regret. Dr Reginald Fisher was welcomed to a seat on the Court. Sir Cecil Wakely was re-elected representative of the Society on the Governing Body of the British Postgraduate Medical Federation.

The following diplomas were granted:

MASTER OF MIDWIFERY—G H Hall, R Hodgkinson, J I Miller, C M Stacey, G F Newbold, M O Will.  
DIPLOMA IN INDUSTRIAL HEALTH—J N Heafes, W A B Reynard, F Wrigley, S J M Walker, D G Robinson, C H Hoskyn.  
LMSSA—V E S Rolfe, P G Green, F R Walker, O B Beardsley, G Copper, E R Eitlinger, J A W Berryman, B Newton, J S Swift, K H Ghorbali, A C Boje, N Rivers, D Davis, A D Griffith, S P Lapage, A I Bervitz, N B Kenyon, W Bust, N Kacas, D F Little, R J F Moore, A J Glyn, M V Salmon, W B Wolstenholme, W Winterstein, R J H Snelson.

## The Services

Major-General A H Harty, CIE, late IMS, has relinquished the appointment of Honorary Physician to the King on retirement.

Major General D V O'Malley, CB, OBE, IMS, has relinquished the appointment of Honorary Surgeon to the King, on retirement.

Colonel (Temporary Brigadier) W H B Bull, OBE, ED, Royal New Zealand A M C, has been appointed Honorary Surgeon to the King in succession to Colonel K McCormick, CB, CBE, DSO, ED, who has been posted to the Reserve of Officers.

Colonel (Temporary Major-General) F K Norns, CBE, DSO, ED, A A M C, and Colonel R D King, CBE, DSO, Royal New Zealand A M C, have been appointed Honorary Physicians to the King in succession to Major General S R Burston, CB, CBE, DSO, ED, A A M C, retired, and Colonel F T Bowerbank, KBE, MC, ED, retired, respectively.

In Circular 140/48 the Ministry of Health has drawn the attention of county district councils to the fact that in accordance with the Tenth Schedule of the National Health Service Act, 1946, the medical officer of health of the council is now required to send to the county council, as local health authority, a copy of a notification of infectious disease within 12 hours of its receipt. This applies to notifications received under Sections 144, 146, and 242 of the Public Health Act, 1936, or of any infectious disease occurring in a common lodging house. The wording of the passage referred to in the Tenth Schedule of the National Health Service Act does not specifically extend to such infectious diseases as have from time to time been made notifiable by regulations under Section 143 of the Public Health Act (or earlier enactment). But the Ministry considers it necessary that for these diseases also copies of notifications should be sent to the county council in the same way.

No 33

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug 14

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

† Deaths from measles and scarlet fever for England and Wales (London (administrative county)) will no longer be published

‡ Includes primary form for England and Wales (London (administrative county)) and Northern Ireland

§ The number of deaths from polio-myelitis and polio-encephalitis for England and Wales (London (administrative county)) are combined

|| Includes puerperal fever for England and Wales and Eire

The return of births and deaths in Eire for the weeks ended Aug 7 and 14 has not been received

## EPIDEMIOLOGICAL NOTES

## German Vital Statistics

According to the *Monthly Statistical Bulletin* (June, 1948) of the Control Commission for Germany (British Element) the provisional result of the population census at Oct 29, 1946, showed that the population of Germany was 65,898,900, of which 22,344,900 are in the British Zone and 605,300 in the British Sector of Berlin. In the first quarter of 1948 the infant mortality rate in the British Zone was 90 and the neonatal rate was 39. The comparable figures in the British Sector of Berlin were 107 and 49. During May, 1948, the daily average percentage of occupied beds in hospitals in the British Zone were as follows: general hospitals 87, hospitals for infectious diseases 68, hospitals for nervous disorders 95, hospitals for children's diseases 88, tuberculosis hospitals 93.

## Discussion of Table

In *England and Wales* a decrease in the number of notifications was reported for measles 982, scarlet fever 74, acute pneumonia 81, and paratyphoid fever 28, while only whooping-cough 273 increased in incidence.

The incidence of measles continued to fall throughout the country, the largest falls during the week were London 143 and Yorkshire West Riding 115. A small decrease in the notifications of scarlet fever was general but no large local variations occurred.

The largest increases in the incidence of whooping-cough were Yorkshire West Riding 68, Lancashire 61, and Sussex 38. The notifications of diphtheria during each of the last three weeks have fallen to a new record low level. The largest returns of diphtheria during the week were Lancashire 18, London 14, and Durham 13.

Outbreaks of dysentery notified during the week were in Surrey, Coulsdon and Purley UD, 24 and Oxfordshire 9. The other large centres of dysentery were London 15, Warwickshire 15 (Warwick RD 10), and Lancashire 11. Notifications of acute poliomyelitis have been practically constant during the past five weeks, and the largest returns during the week were Lancashire 4, Middlesex 4, Yorkshire West Riding 4 (Sheffield CB 2), Glamorganshire 3 (Cardiff RD 2) and Kent 3, 2 cases were notified from Essex, West Ham CB.

In *Scotland* the chief feature of the returns was an increase of 20 in the notifications of dysentery. The largest centres of infection were Glasgow 25 and Edinburgh 10.

In *Eire* a decreased incidence was recorded for diarrhoea and enteritis 15 and whooping-cough 24, while increases were reported for scarlet fever 16.

In *Northern Ireland* only small fluctuations were reported in the trends of infectious diseases. An outbreak of poliomyelitis affecting 11 persons was announced by the Ministry of Health on Aug 16.

## Week Ending August 21

The notifications of infectious diseases in England and Wales during the week included scarlet fever 736, whooping-cough 3,260, diphtheria 116, measles 4,611, acute pneumonia 266, cerebrospinal fever 26, acute poliomyelitis 72, dysentery 111, paratyphoid fever 20, typhoid fever 8.

## Medical News

## Prize Essay on Colonial Tuberculosis

A prize of one hundred guineas will be awarded by the National Association for the Prevention of Tuberculosis for an essay on 'The Control of Tuberculosis in a British Colony'. The competition is open to doctors in the British Colonial Medical Service who are of not more than ten years' or less than five years' medical standing, of which at least three years have been spent overseas in a medical capacity. Competitors should describe their own proposals for a practical scheme for the clinical, social, and administrative control of tuberculosis, either in the British Colonies as a whole or in one or more of them separately. Writers should give their own opinions based on personal experience of public health and anti-tuberculosis work. Essays should reach Dr Harley Williams, N.A.P.T., not later than March 1, 1949. Award of the prize will be notified at the N.A.P.T. Commonwealth and Empire Conference, which is to be held in London in July, 1949.

## Unesco Publication

Unesco has issued a 'List of Scientific Papers Published in the Middle East'. The introduction is in French and English, and the titles of papers in Arabic are translated into one of these languages. The list includes those papers received by Unesco up to March 1 of this year.

**Extra Rations for Tuberculous Patients**

The Ministry of Food has announced that patients with active tuberculosis who are receiving additional allowances of milk, bacon, and cooking fat are to be granted an extra three ounces of butter or margarine and an extra three eggs a week. Patients who are eligible for this extra food can obtain the necessary permit by taking or sending their ration books to their local food office.

**Whitley Council for Nurses**

The names of the representatives of the management and staff sides of the Whitley Council for Nurses and Midwives were published in the *Supplement* of Aug 21 (p 89). The name of Dr R H H Jolly, medical officer of health of Wolverhampton, should be added as the second representative of the Association of Municipal Corporations.

**School Meals Service**

The National Council of Social Service has just published a booklet, *The Social History of the School Meals Service* by Mr F Le Gros Clark. The author traces the development of school meals as a new social institution. At the end of the nineteenth century school meals were regarded as an occasional charity for poor children. The changes which have taken place from then to the present day are fully described and some of the more recent developments are illustrated. Copies of the booklet (price 2s) may be obtained from the National Council of Social Service, 26, Bedford Square, London, WC1.

**COMING EVENTS****Refresher Courses in Paris**

Refresher courses in medicine, surgery, and the specialties will be held in October at the Hôpital Bichat, Paris, XVIIIe. Further information may be obtained from Expansion Scientifique Française, 23, rue de Cherche Midi, Paris.

**Congress of Biological Chemistry**

The 8th Congress of Biological Chemistry will be held in Paris on Oct 6-8. Information may be obtained from M Jean Courtois, Secrétariat du Congrès, 4, Avenue de l'Observatoire, Paris, VIe.

**Refresher Courses in Tuberculosis**

The National Association for the Prevention of Tuberculosis has arranged the following refresher courses: "Radiology in Connection with Tuberculosis and Chest Diseases," at Leeds University, Sept 20-22. Fee, £4 4s, limited inclusive accommodation at Leeds University Hostel, £2 15s. "The Treatment of Non-pulmonary Tuberculosis, including Lupus," at Lord Mayor Treloar Cripples' Hospital, Alton, Hants, Oct 5-7. Fee, £3 3s, reserved hotel accommodation approximately £1 1s per day, dinner, bed, and breakfast. Course limited to 16. Clinical Courses at the Cheshire Joint Sanatorium, Market Drayton, Salop, Oct 26-28, Nov 23-25, and Dec 7-9. Fee £3 3s, hotel accommodation in Market Drayton can usually be obtained at approximately £1 1s per day, dinner, bed, and breakfast. Courses limited to four.

**Health Education Courses for Public Health Nurses**

The Central Council for Health Education is arranging two day courses of lectures on the subject of health education for health visitors, midwives, district nurses, school nurses, etc., in the under-mentioned university centres: Birmingham, Sept 13-14, Bristol, Nov 1-2, Cambridge, Oct 18-19, Cardiff, Oct 25-26, Leeds, Oct 4-5, Liverpool, Sept 20-21, Manchester, Sept 23-24, Newcastle, Oct 14-15, Oxford, Oct 11-12, Sheffield, Oct 7-8. Courses are also arranged in Belfast, London, Middlesex, Essex, Kent, and Surrey, particulars of which can be obtained from the Medical Adviser and Secretary of the Central Council for Health Education, Tavistock House, Tavistock Square, London, WC1. Under the general title of Health Education, lectures will be given on physiology, psychology, social factors affecting health, child health, educational methods, and the practice of health education. A member of the staff of the Central Council will take part in each course, but the majority of the lectures will be given by appropriate senior members of university staffs. No charge will be made for nurses nominated by officers of local authorities, to whom application to attend should be made.

**Radioactivity in Inorganic Chemistry**

Three postgraduate lectures on "The Impact of Radioactivity in Inorganic Chemistry" will be delivered by Professor H J Emeléus, FRS, on Sept 30, Oct 7, and Oct 14 at the Royal Institution, 21, Albemarle Street, London, W1. Admission will be by ticket (10s for the three lectures) obtainable from Mr H C Worsdall, London Section, O.C.C.A., c/o Plastanol, Ltd., Crabtree Manorway, Belvedere, Kent. Junior members may attend free but must apply for complimentary tickets.

**SOCIETIES AND LECTURES****Tuesday**

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY 330 Gray's Inn Road, London, WC, Sept 7, 9.30 a.m. *Non-operative Treatment of Maxillary Sinusitis* by Mr Myles L. Formby.

**Friday**

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Anatomy Lecture Theatre, Edinburgh University, Sept 10, 3.30 p.m. *'Localization of Cerebral Function'* by Dr W. Ritchie Russell.

**APPOINTMENTS**

DICKIE G G MB ChB, DPH Medical Officer of Health Barrow in Furness.

MOORE E H MB ChB DPH Medical Officer of Health for Sale and Lymm and Divisional Medical Officer and School Medical Officer for Cheshire.

**BIRTHS, MARRIAGES, AND DEATHS****BIRTHS**

Essex-Cater—On Aug 11 1948 at Paddington Hospital to Jane (née Binning) wife of Dr Antony Essex-Cater F.R.A.I. a son—Jonathan.  
Graves—On Aug 23 1948 to Valerie wife of Dr J C Graves a son.  
Quinn—On Aug 24 1948 to Mary (née McKenna) wife of Dr Brian S Quinn of 116 Kenilworth Gardens Westcliff-on-Sea a son—Niall Patrick.

**DEATHS**

Alderson—On May 29 1948 Esther Violet Alderson (née Adderley) MB BCh Dublin.  
Berry—On Aug 26 1948 Noel William Berry MRCS LRCP of Langton House Bury Road Alverstoke Hants.  
Brogden—On Aug 27 1948 at Braekendale Maybury Woking Surrey George Alexander Brogden M.D. Ed. aged 78.  
Burton—On Aug 23 1948 at Oakdale Frodsham Cheshire William Edward Burton JP MRCS LRCP DPH aged 82.  
Carver—On Aug 25 1948 at Sutton Courtenay John Robertson Carver M.D. DPH.  
Cobban—On Aug 21 1948 at an Edinburgh nursing home Alexander Lee Cobban MB CM.  
Cuff—On Aug 17 1948 at Nicosia Cyprus Cyril Charles Herbert Cuff OBE FRCS Ed.  
Higgs—On Aug 12 1948 at St Leonards-on-Sea Walter Alpheus Higgs MRCS LRCP.  
Jamieson—On Aug 20 1948 at 8 Waltham Terrace Blackrock Dublin John Kay Jamieson Hon LL.D. MB CM Ed. late Professor of Anatomy Trinity College Dublin and Leeds University.  
Leggatt—On Aug 24 1948 at 11 Devonshire Road West Kirby, Archibald Renwick Leggatt MB ChB Ed. late of Manchuria aged 71.  
Lowbury—On Aug 24 1948 at 21 Menelik Road London NW Benjamin William Lowbury M.D.  
Lowe—On Aug 18 1948 Percy Roycroft Lowe OBE MB late of the British Museum (Natural History) aged 78.  
Lowry—On Aug 20 1948 James Arthur Lowry MD RUJ of 49 High Street Fareham Hants.  
MacLagan—On Aug 18 1948 at Port Lodge Dunbar Donald Robert Clarke MacLagan MB ChB Ed.  
Manby—On Aug 19 1948 Walter Edward Manby MB BC of Pembroke aged 83.  
Nesbitt—On Aug 17 1948 Charles van Homrigh Nesbitt MD of Liverpool Road North Maghull Liverpool aged 84.  
Parmiter—On Aug 19 1948 at the Victoria Cottage Hospital Wimborne Dorset Bernard Rayne Parmiter MB BS.  
Pereval—On Aug 19 1948 at 28 Branksome Wood Road Bournemouth John Lansdowne Pereval MRCS LRCP dearly loved husband of Winifred late of Childe Okford Dorset aged 61.  
Pugh—On Aug 19 1948 Stephen Horatio Pugh FRCS Ed. of Maes v-Coed Builth Wells Breconshire.  
Pym—On Aug 5 1948 at Burwood NSW Australia Charles Brownlow Pym MRCS LRCP.  
Ritchie—On Aug 20 1948 at Sheffield Royal Infirmary Alexander Ritchie MB ChB DPH.  
Roberts—On Aug 25 1948 at The Croft Brox Road Ottershaw James Ernest Helme Roberts OBE FRCS.  
Thomas—On July 30 1948 Robert Evans Thomas MD DPH of Bath aged 66.  
Yong—On Aug 28 1948 at Hazeldon Tavistock Devon Augustus Henry Owen Young LRCP & SI and LM Lieutenant-Colonel R.A.M.C. retired.
